Abstract `HERAFitter` [1] is an open-source package which provides a framework for the determination of the parton distribution functions (PDFs) of the proton and for many different kinds of analyses in Quantum Chromodynamics (QCD).

Measurements of lepton-proton deep inelastic scattering and of proton-proton (proton-antiproton) collisions at hadron colliders are included in the `HERAFitter` package, and are used to probe and constrain the partonic content of the proton.

The parton distribution functions are determined by using the factorisation properties of the hadron cross sections in which short-distance perturbatively calculable parton scattering cross sections and the non-perturbative universal PDFs, are factorised.

The `HERAFitter` platform provides a common environment for QCD analyses using a variety of theoretical calculations and methodological options. A broad range of options for the treatment of the experimental uncertainties is also provided. The general structure of `HERAFitter` together with the choices of options available within it are described in this paper.

1 Introduction

The recent discovery of the Higgs boson [7, 8] and the extensive searches for signals of new physics in LHC proton-proton collisions demand high-precision calculations and computations to test the validity of the Standard Model (SM) and factorisation in Quantum Chromodynamics (QCD). Using collinear factorisation, hadron inclusive cross sections may be written as

$$\sigma(\alpha_s(\mu_R^2),\mu_R^2,\mu_F^2) = \sum_{a,b}\int_0^1 dx_1\, dx_2 f_a(x_1,\mu_F^2) f_b(x_2,\mu_F^2) \times \hat{\sigma}^{ab}(x_1,x_2;\alpha_s(\mu_R^2),\mu_R^2,\mu_F^2), \quad (1)$$

where the cross section σ is expressed as a convolution of Parton Distribution Functions (PDFs) f_a and f_b with the parton cross section $\hat{\sigma}^{ab}$. At Leading-Order (LO), the PDFs represent the probability of finding a specific parton a (b) in the first (second) proton carrying a fraction x_1 (x_2) of its momentum. The indices a and b in the Eq. 1 indicate the various kinds of partons, i.e. gluons, quarks and antiquarks of different flavours, that are considered as the constituents of the proton. The PDFs depend on factorisation scale, μ_F, while the parton cross sections depend on the strong coupling, α_s, and the factorisation and renormalisation scales, μ_F and μ_R. The parton cross sections $\hat{\sigma}^{ab}$ are calculable in pQCD whereas PDFs are non-perturbative and are thus constrained by global fits to a variety of experimental data. The assumption that PDFs are universal, within a particular factorisation scheme [9–13], is crucial to this procedure. Recent review articles on PDFs can be found in Refs. [14, 15].

Accurate determination of PDFs as a function of x requires large amount of hard-process experimental data, covering a wide kinematic region and sensitive to different kinds of partons. Measurements of the inclusive Neutral Current (NC) and Charge Current (CC) Deep Inelastic Scattering (DIS) at the ep collider HERA provide crucial information for determining the PDFs. Hard processes in pp and $p\bar{p}$ collisions at the LHC and the Tevatron, respectively, provide complementary information to the DIS measurements. The PDFs are determined from χ^2 fits of the theoretical predictions to the data [16–20]. The rapid flow of new data from the LHC experiments and the corresponding theoretical developments, which are providing predictions for more complex processes at increasingly higher orders, has motivated the development of a tool to combine them together in a fast, efficient, open-source platform.

This paper describes the open-source QCD fit platform `HERAFitter` which includes a set of tools designed to facilitate comprehensive global QCD analyses of pp, $p\bar{p}$ and ep scattering data. It has been developed for the determination of PDFs and the extraction of fundamental QCD parameters such as the heavy quark masses and the strong coupling constant. It also provides a common platform for comparison of different theoretical approaches. Furthermore, it can be used for direct tests of the impact of new experimental data on the PDFs and on the SM parameters.

This paper is organised as follows. The structure and overview of `HERAFitter` are presented in Section 2. In Section 3 the various processes available in `HERAFitter` and the corresponding theoretical calculations, performed within the framework of collinear factorisation and the DGLAP [21–25] formalism, are discussed. In Section 4 tools for fast calculations of the theoretical predictions used in `HERAFitter` are presented. In Section 5 the methodology of determining PDFs through fits based on various χ^2 definitions is explained. In particular, different treatment of correlated experimental uncertainties are presented. Alternative approaches to the DGLAP formalism are presented in Section 6. The `HERAFitter` code organisation is discussed in Section 7, specific applications of the package are given in Section 8 and a summary is presented in Section 9.

Experimental Data	**Process**	**Reaction**	**Theory calculations, schemes**
HERA, Fixed Target	DIS NC	$ep \to eX$	TR′, ACOT, ZM (`QCDNUM`), FFN (`OPENQCDRAD`, `QCDNUM`), TMD (uPDFevolv)
HERA	DIS CC	$ep \to \nu_e X$	ACOT, ZM (`QCDNUM`), FFN (`OPENQCDRAD`)
	DIS jets	$ep \to e$ jets$X$	`NLOJet++` (`fastNLO`)
	DIS heavy quarks	$ep \to ec\bar{c}X$, $ep \to eb\bar{b}X$	ZM (`QCDNUM`), TR′, ACOT, FFN (`OPENQCDRAD`, `QCDNUM`)
Tevatron, LHC	Drell-Yan	$pp(\bar{p}) \to l\bar{l}X$, $pp(\bar{p}) \to l\nu X$	`MCFM` (`APPLGRID`)
	top pair	$pp(\bar{p}) \to t\bar{t}X$	`MCFM` (`APPLGRID`), `HATHOR`
	single top	$pp(\bar{p}) \to tl\nu X$, $pp(\bar{p}) \to tX$, $pp(\bar{p}) \to tWX$	`MCFM` (`APPLGRID`)
	jets	$pp(\bar{p}) \to$ jets$X$	`NLOJet++` (`APPLGRID`), `NLOJet++` (`fastNLO`)
LHC	DY+heavy quarks	$pp \to VhX$	`MCFM` (`APPLGRID`)

Table 1 The list of experimental data and theory calculation implemented in the `HERAFitter` package. The references for the individual calculations and schemes are given in the text.

2 The HERAFitter Structure

In this section the functionality of `HERAFitter` is described. A block diagram in Fig 1 illustrates the schamatical view of the `HERAFitter` functionality which can be divided into four main blocks:

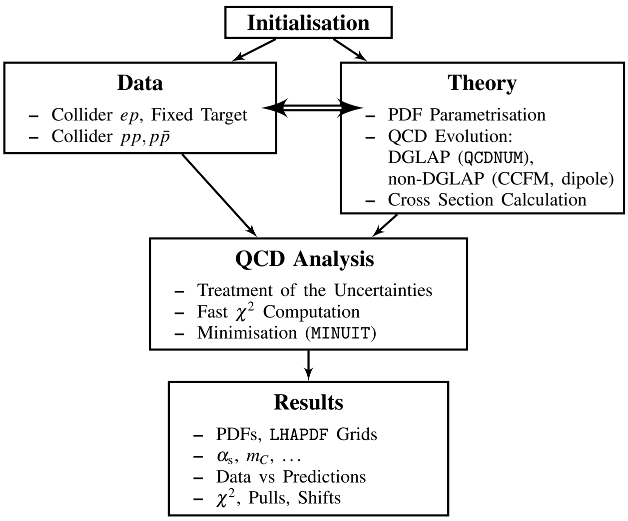

Fig. 1 Schematic structure of the `HERAFitter` program.

Data: Different available measurements from various processes are implemented in the `HERAFitter` package including the full information on their uncorrelated and correlated uncertainties. HERA data are sensitive to light quark and gluon densities mostly through scaling violations, covering low and medium x ranges. These data are the basis of any proton PDF extraction, and are used by all global PDF groups [16–20]. However, improvements in precision of PDFs require additional constraints on the gluon and quark distributions at high-x, better understanding of heavy quark distributions and decomposition of the light-quark sea. For these purposes, the measurements of the fixed-target experiments, Tevatron and LHC are of particular importance. The processes that are currently available in `HERAFitter` framework are listed in Tab. 1.

Theory: Predictions for cross section of different processes are obtained using the factorisation approach (Eq. 1). The PDFs are parametrised at a starting input scale Q_0^2 by a chosen functional form with a set of free parameters $\mathbf{p}$. These PDFs are evolved to the scale of the measurement Q^2, $Q^2 > Q_0^2$. The evolution follows either DGLAP [21–25] (as implemented in `QCDNUM` [26]) or CCFM [27–30] (as implemented in `uPDFevolv` [31]). The prediction of a cross section of a particular process is obtained by a convolution of the evolved PDFs and the partonic cross section, calculated at a certain order in QCD with a appropriate theory calculation (as listed in Tab. 1). Alternatively, predictions using dipole models [32–34] can be also obtained.

QCD analysis: The PDFs are determined by the least square fit, minimising the χ^2 function, formed using the input data and theory predictions, with the `MINUIT` [35] program. Various choices of accounting for the experimental uncertainties are employed in `HERAFitter`, either using a nuisance parameter method for the correlated systematic uncertainties, or a covariance matrix method as described in section 5.2. In addition, HERAFitter allows to study different statistics assumptions for the distributions of the systematic uncertainties, like Gauss, LogNormal [36] (see section 5.3).

Results: The resulting PDFs are provided in a format ready to be used by the LHAPDF library [37, 38] or by TMDlib [39]. HERAFitter drawing tools can be used to display the PDFs with their uncertainties at a chosen scale. As an example, a first set of PDFs extracted using HERAFitter from HERA I data, HERAPDF1.0 [40], is shown in Fig. 2 (taken from [40]).

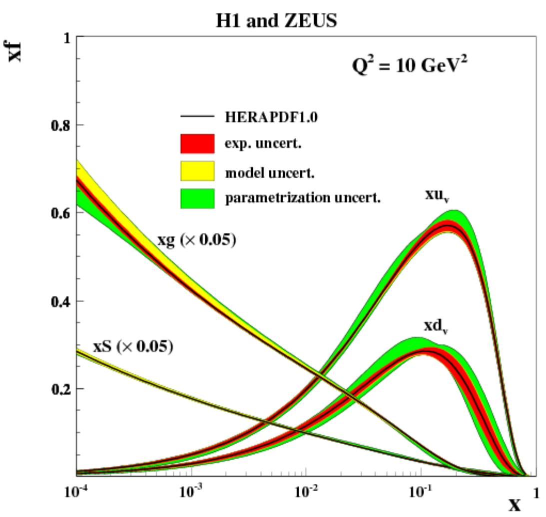

Fig. 2 Distributions of valence (xu_v, xd_v), sea (xS) and the gluon (g) densities in HERAPDF1.0 [40]. The gluon and the sea distributions are scaled down by a factor of 20. The experimental, model and parametrisation uncertainties are shown as coloured bands.

3 Theoretical formalism using DGLAP evolution

In this section the theoretical formalism based on DGLAP [21–25] evolution is described.

A direct consequence of factorisation (Eq. 1) is that scale dependence or "evolution" of the PDFs can be predicted by the renormalisation group equations. By requiring that physical observables are independent of $\mu_{\rm F}$, a representation of parton evolution in terms of the DGLAP equations:

$$\frac{d\, f_a(x,\mu_{\rm F}^2)}{d\log\mu_{\rm F}^2} = \sum_{b=q\bar{q},g} \int_x^1 \frac{dz}{z} P_{ab}\left(\frac{x}{z};\mu_{\rm F}^2\right) f_b(z,\mu_{\rm F}^2)\,, \tag{2}$$

where the functions P_{ab} are the evolution kernels or splitting functions, which represent the probability of finding parton a in parton b. They can be calculated as a perturbative expansion in α_s. Once PDFs are determined at the initial scale Q_0^2, their evolution to any other scale $Q^2 > Q_0^2$ is entirely determined by the DGLAP equations. The PDFs are then used to calculate cross sections for various different processes. Alternative approaches to DGLAP evolution, valid in different kinematic regimes, are also implemented in HERAFitter and will be discussed in the next sections.

3.1 Deep Inelastic Scattering and Proton Structure

The formalism that relates the DIS measurements to pQCD and the PDFs has been described in detail in many extensive reviews (see e.g. Ref. [41]) and it is only briefly summarised here. DIS is the process where a lepton scatters off the partons in the proton by a virtual exchange of a NC (neutral current) or CC (charged current) vector boson and, as a result, a scattered lepton and a multi-hadronic final state are produced. The common DIS kinematic variables are the scale of the process Q^2, the absolute squared four-momentum of the exchange boson, Bjorken x, which can be related in the parton model to the fraction of momentum carried by the struck quark, and the inelasticity y. These are related by $y = Q^2/sx$, where s is the squared centre-of-mass (c.o.m.) energy.

The NC cross section can be expressed in terms of generalised structure functions:

$$\frac{d^2\sigma_{NC}^{e^\pm p}}{dxdQ^2} = \frac{2\pi\alpha^2}{xQ^4}\cdot\sigma_{r,NC}^{e^\pm p}, \tag{3}$$

$$\sigma_{r,NC}^{e^\pm p} = Y_+\tilde{F}_2^\pm \mp Y_- x\tilde{F}_3^\pm - y^2\tilde{F}_L^\pm, \tag{4}$$

where $Y_\pm = 1\pm(1-y)^2$ and the electromagnetic coupling constant α, the photon propagator and a helicity factor are absorbed in the definition of the reduced cross section σ_r. The generalised structure functions $\tilde{F}$ can be written as linear combinations of the proton structure functions $F^\gamma, F^{\gamma Z}$ and F^Z, which are associated to pure photon exchange terms, photon-Z interference terms and pure Z exchange terms, respectively. The structure function $\tilde{F}_2$ is the dominant contribution to the cross section, $x\tilde{F}_3$ becomes important at high Q^2 and $\tilde{F}_L$ is sizable only at high y. In the framework of pQCD the structure functions are directly related to the PDFs, i.e. in leading order (LO) F_2 is the weighted momentum sum of quark and anti-quark distributions, $F_2 \approx x\sum e_q^2(q+\overline{q})$, xF_3 is related to their difference, $xF_3 \approx x\sum 2e_q a_q(q-\overline{q})$ (where a_q is the axial-vector quark coupling and e_q the quark electric charge) and F_L vanishes. At higher orders, terms related to the gluon density distribution ($\alpha_s g$) appear, in particular F_L is strongly related to the low-x gluon.

The inclusive CC ep cross section, analogous to the NC case, can be expressed in terms of another set of structure functions, $\tilde{W}$: :

$$\frac{d^2\sigma_{CC}^{e^\pm p}}{dxdQ^2} = \frac{1\pm P}{2}\frac{G_F^2}{2\pi x}\left[\frac{M_W^2}{M_W^2+Q^2}\right]\cdot\sigma_{r,CC}^{e^\pm p} \tag{5}$$

$$\sigma_{r,CC}^{e^\pm p} = Y_+\tilde{W}_2^\pm \mp Y_- x\tilde{W}_3^\pm - y^2\tilde{W}_L^\pm, \tag{6}$$

where P represents the lepton beam polarisation. At LO in α_s, the CC e^+p and e^-p cross sections are sensitive to different combinations of the quark flavour densities.

$$\sigma_{r,CC}^{e^+p} \approx x[\overline{u}+\overline{c}] + (1-y)^2 x[d+s], \quad (7)$$

$$\sigma_{r,CC}^{e^-p} \approx x[u+c] + (1-y)^2 x[\overline{d}+\overline{s}], \quad (8)$$

Here U and D denote the sum over up- and down-type quarks; the latter include also strange and beauty quarks and the former charm quarks.

Beyond LO, the QCD predictions for the DIS structure functions are obtained by convoluting the PDFs with appropriate hard-process scattering matrix elements, which are referred to as coefficient functions.

The DIS measurements span a large range of Q^2 from few GeV^2 to about 10^5 GeV^2, crossing heavy-quark mass thresholds, thus the treatment of heavy quark (charm and beauty) production and the chosen values of their masses becomes important. There are different approaches to the treatment of heavy quark production that would be equivalent if calculations could be carried out to all orders in α_s, but which differ at finite order. Several variants of these schemes are implemented in `HERAFitter` and they are briefly discussed below.

Zero-Mass Variable Flavour Number (ZM-VFN)[2]: In this scheme, the heavy quarks appear as partons in the proton at Q^2 values above $\sim m_h^2$ (heavy quark mass) and the heavy quarks are then treated as massless in both the initial and final states of the hard scattering process. The lowest order process is the scattering of the lepton off the heavy quark via (electroweak) boson exchange. This scheme is expected to be reliable in the region with $Q^2 \gg m_h^2$. In `HERAFitter` this scheme is available for the DIS structure function calculation via the interface to the `QCDNUM` [26] package, thus it benefits from the fast `QCDNUM` convolution engine.

Fixed Flavour Number (FFN)[3–5]: In this scheme only the gluon and the light quarks are considered as partons within the proton and massive quarks are produced perturbatively in the final state. The lowest order process is the heavy quark-antiquark pair production via boson-gluon fusion. In `HERAFitter` this scheme can be accessed via the `QCDNUM` implementation or through the interface to the open-source code `OPENQCDRAD` [42], as implemented by the ABM group. This scheme is reliable for $Q^2 \sim m_h^2$. In `QCDNUM`, the calculation of the heavy quark contributions to DIS structure functions are available at Next-to-Leading-Order (NLO) and only electromagnetic exchange contributions are taken into account. In the `OPENQCDRAD` implementation the heavy quark contributions to CC structure functions are also available and, for the NC case, the QCD corrections to the massive Wilson coefficients at Next-to-Next-to Leading Order (NNLO) and, for the NC case, the QCD corrections to the coefficient functions at Next-to-Next-to Leading Order (NNLO) are provided at the best currently known approximation [43]. The `OPENQCDRAD` implementation also uses the running heavy-quark mass [44] in the $\overline{\text{MS}}$ scheme. This scheme has the advantage of reducing the sensitivity of the DIS cross sections to higher order corrections, and improving the theoretical precision of the mass definition.

General-Mass Variable Flavour Number (GM-VFN)[6]: In these schemes, heavy quark production is treated for $Q^2 \sim m_h^2$ in the FFN scheme and for $Q^2 \gg m_h^2$ in the massless scheme with a suitable interpolation inbetween. The details of this interpolation differ between different implementations. The PDF groups that use GM-VFN schemes are MSTW, CT(CTEQ), NNPDF, and HERAPDF. `HERAFitter` implements different variants of the GM-VFN scheme and they are presented below:

- *GM-VFN Thorne-Roberts scheme:* The Thorne-Roberts (TR) scheme [45] was designed to provide a smooth transition from the massive FFN scheme at low scales $Q^2 \sim m_h^2$ to the massless ZM-VFNS scheme at high scales $Q^2 \gg m_h^2$. However, the original version was technically difficult to implement beyond NLO, and was updated to the TR$'$ scheme [46]. There are two different variants of the TR$'$ schemes: TR$'$ standard (as used in MSTW PDF sets [16, 46]) and TR$'$ optimal [47], with a smoother transition across the heavy quark threshold region. Both variants are accessible within the `HERAFitter` package at LO, NLO and NNLO.
- *GM-VFN ACOT scheme:* The Aivazis-Collins-Olness-Tung (ACOT) scheme belongs to the group of VFN factorisation schemes that use the renormalisation method of Collins-Wilczek-Zee (CWZ) [48]. This scheme unifies the low scale $Q^2 \sim m_h^2$ and high scale $Q^2 > m_h^2$ regions with a smooth interpolation across the full energy range. Within the ACOT package, different variants of the ACOT scheme are available: ACOT-Full [49], S-ACOT-χ [50, 51], ACOT-ZM [49], $\overline{\text{MS}}$ at LO and NLO. For the longitudinal structure function higher order calculations are also available. A comparison of PDFs extracted from the QCD fits to the HERA data with the TR$'$ and ACOT-Full schemes is illustrated in Fig. 3 (taken from [40]).

3.2 Electroweak Corrections to DIS

Calculations of higher-order electroweak corrections to DIS scattering at HERA are available in `HERAFitter` in the on-shell scheme. In this scheme the gauge bosons masses M_W and M_Z are treated as basic parameters together with the top, Higgs and fermion masses. These electroweak corrections are based on the `EPRC` package [52]. The code calculates the

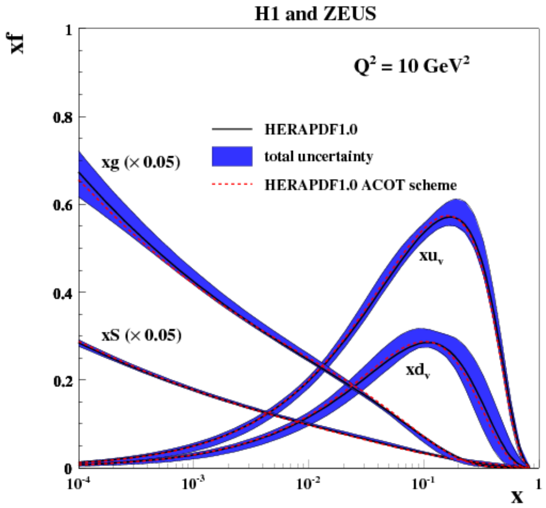

Fig. 3 Overview showing the u- and d-valence, the total sea (scaled), and gluon (scaled) PDFs of the NLO HERAPDF1.0 set [40] with their total uncertainty at the scale of $Q^2 = 10$ GeV^2 obtained using the TR$'$ scheme and compared to the PDFs obtained with the ACOT scheme using the k-factor technique (red).

running of the electromagnetic coupling α using the most recent parametrisation of the hadronic contribution [53], as well as an older version from Burkhard [54].

3.3 Diffractive PDFs

Diffractive parton distributions (DPDFs) can be determined from QCD fits to diffractive cross sections in a similar way to the determination of the standard PDFs. About 10% of deep inelastic interactions at HERA are diffractive, such that the interacting proton stays intact ($ep \to eXp$). The proton is well separated from the rest of the hadronic final state by a large rapidity gap. This is interpreted as the dissociation of the virtual photon into hadronic system X with an invariant mass much smaller than the photon-proton c.o.m. energy $W = ys - Q^2 + m_p^2(1-y)$, where m_p is proton's mass. Such a process is assumed to be mediated by the exchange of a hard Pomeron or a secondary Reggeon with vacuum quantum numbers. This factorisable pomeron picture has proved remarkably successful in the description of most of the diffractive data.

In addition to the usual DIS variables x, Q^2, extra kinematic variables are needed to describe the diffractive process. These are the squared four-momentum transfer of the exchange Pomeron or Reggeon, t, and the mass M_X of the diffractively produced final state. In practice, the variable M_X is often replaced by dimensionless quantity $\beta = \frac{Q^2}{M_X^2+Q^2-t}$. In models based on a factorisable pomeron, β may be viewed at LO as the fraction of the pomeron longitudinal momentum which is carried by the struck parton, $x = \beta x_{IP}$.

For the inclusive case, the diffractive cross-section reads as:

$$\frac{d\sigma}{d\beta\, dQ^2 dx_{IP}\, dt} = \frac{2\pi\alpha^2}{\beta Q^4}\left(1+(1-y)^2\right)\overline{\sigma}^{D(4)}(\beta,Q^2,x_{IP},t) \quad (9)$$

with the "reduced cross-section":

$$\overline{\sigma}^{D(4)} = F_2^{D(4)} - \frac{y^2}{1+(1-y)^2}F_L^{D(4)}. \quad (10)$$

Substituting $x = x_{IP}\beta$ we can relate Eq. 9 to the standard DIS formula. In this way, the diffractive structure functions can be expressed as convolutions of calculable coefficient functions with the diffractive quark and gluon distribution functions, which in general depend on x_{IP}, Q^2, β, t.

The diffractive PDFs in `HERAFitter` [55, 56] are implemented as a sum of two factorised contributions:

$$\Phi_{IP}(x_{IP},t)\, f_a^{Pom}(\beta,Q^2) + \Phi_{IR}(x_{IP},t)\, f_a^{IR}(\beta,Q^2), \quad (11)$$

where $\Phi(x_{IP},t)$ are the Reggeon and Pomeron fluxes. The Reggeon PDFs, f_a^{IR} are fixed as those of the pion, while the Pomeron PDFs, f_a^{IP}, can be obtained from a fit to the data.

3.4 Drell-Yan Processes in pp or $p\bar{p}$ Collisions

Drell-Yan process provides further valuable information about PDFs. In pp and $p\bar{p}$ scattering, the Z/γ^* and W production probe bi-linear combinations of quarks. Complementary information on the different quark densities can be obtained from the W asymmetry (d, u and their ratio), the ratio of the W and Z cross sections (sensitive to the flavour composition of the quark sea, in particular to the s-quark density), and associated W and Z production with heavy quarks (sensitive to s- and c-quark densities). Measurements at large boson $p_T \gtrsim M_{W,Z}$ are potentially sensitive to the gluon density [57].

At LO the DY NC triple differential cross section in invariant mass M, boson rapidity y and lepton scattering angle $\cos\theta$ in the parton c.o.m. frame can be written as [58, 59]:

$$\begin{aligned}\frac{d^3\sigma}{dMdy\,d\cos\theta} &= \frac{\pi\alpha^2}{3MS}\sum_q \hat{\sigma}^q(\cos\theta,M)\\ &\times\left[f_q(x_1,Q^2)f_{\bar{q}}(x_2,Q^2)+(q\leftrightarrow\bar{q})\right], \end{aligned}\quad (12)$$

where S is the squared c.o.m. beam energy, the parton momentum fractions are given by $x_{1,2} = \frac{M}{\sqrt{S}}\exp(\pm y)$, $f_q(x_1,Q^2)$ are the PDFs, and $\hat{\sigma}^q$ is the parton-parton hard scattering cross section.

The corresponding CC triple differential cross section has the form:

$$\begin{aligned}\frac{d^3\sigma}{dMdy\,d\cos\theta} &= \frac{\pi\alpha^2}{48S\sin^4\theta_W}\frac{M^3(1-\cos\theta)^2}{(M^2-M_W^2)+\Gamma_W^2M_W^2}\\ &\times\sum_{q_1,q_2}V_{q_1q_2}^2 f_{q_1}(x_1,Q^2)f_{q_2}(x_2,Q^2), \end{aligned}\quad (13)$$

where $V_{q_1q_2}$ is the Cabibbo-Kobayashi-Maskawa (CKM) quark mixing matrix and M_W and Γ_W are the W boson mass and decay width, respectively.

The simple form of these expressions allows analytic calculation of integrated cross sections. In both NC and CC expressions the PDFs depend only on boson rapidity y and invariant mass M, while the integral in $\cos\theta$ can be solved analytically even for the case of realistic kinematic cuts.

Beyond LO, the calculations can no longer be done quickly and MC techniques are often employed. Currently, the predictions for W and Z/γ^* production are available up to NNLO and the predictions for W, Z in association with heavy flavour quarks is available to NLO. There are several possibilities for obtaining the theoretical predictions for DY production in `HERAFitter`.

The NLO and NNLO calculations are computing power and time consuming and k-factor or *fast grid* techniques must be employed (see section 4 for details), interfaced to programs such as `MCFM` [60–62], available for NLO calculations, or `FEWZ` [63] and `DYNNLO` [64] for NLO and NNLO.

3.5 Jet Production in ep and pp or $p\bar{p}$ Collisions

The cross section for production of high-transverse-momentum hadronic jets is sensitive to the high-x gluon PDF (see e.g. Ref. [16]) therefore this process can be used to improve the determination of the gluon PDF, which is particularly important for Higgs production and searches for new physics. Jet production cross sections are currently known only to NLO, although calculations for higher-order contributions to jet production in proton-proton collisions are now quite advanced [65–67]. Within `HERAFitter`, the `NLOJet++` program [68, 69] may be used for calculations of jet production. Similarly to the DY case, the calculation is very demanding in terms of computing power. Therefore *fast grid* techniques are used to facilitate the QCD analyses including jet cross section measurements. in ep, pp and $p\bar{p}$ collisions (for details see section 4).

3.6 Top-quark Production in pp or $p\bar{p}$ Collisions

At the LHC top-quark pairs ($t\bar{t}$) are produced at hadron colliders dominantly via gg fusion. Thus LHC Measurements of the $t\bar{t}$ cross sections can provide additional constraints on the gluon density at medium to high values of x, on α_s and on the top-quark mass, m_t [70]. Precise predictions for the total $t\bar{t}$ cross section are available to full NNLO [71]. They can be computed within `HERAFitter` via an interface to the program `HATHOR` [72]. Differential $t\bar{t}$ cross section predictions can be obtained using `MCFM` [62, 73–76] interfaced to `HERAFitter` with *fast grid* techniques.

Single top quarks are produced via electroweak interactions and single-top cross sections can be used, for example, to probe the ratio of the u and d densities in the proton as well as the b-quark PDF. Predictions for single-top production are available to NLO accuracy using `MCFM`.

4 Computational Techniques

Precise measurements require theoretical predictions with equally good accuracy in order to maximise their impact in PDF fits. Perturbative calculations, however, get more and more involved with order due to an increasing number of Feynman diagrams. Nowadays even the most advanced perturbative techniques in combination with modern computing hardware do not lead to sufficiently small turn-around times. The direct inclusion of computationally demanding higher-order calculations into iterative fits therefore is not possible. Relying on the fact that a full repetition of the perturbative calculation for arbitrary changes in input parameters is not necessary at each iteration step, two methods have been developed to resolve this problem: the techniques of k-factors and *fast grids*. Both are available in `HERAFitter` and described as follows.

4.1 k-factor Technique

The k-factors are defined as the ratio of the prediction of a higher-order (slow) pQCD calculation to a lower-order (fast) calculation. Because the k-factors depend on the phase space probed by the measurement, they have to be stored in a table including dependence on the relevant kinematic variables. Before the start of a fitting procedure, the table of k-factors has to be computed once for a given PDF with the time consuming higher-order code. In subsequent iteration steps the theory prediction is derived from the fast lower-order calculation multiplied by the pre-tabulated k-factors.

This procedure, however, neglects the fact that the k-factors can be PDF dependent, as a consequence, they have to be re-evaluated for the newly determined PDF at the end of the fit for the consistency check. Usually, the fit is repeated until input and output k-factors have converged. In summary, this technique avoids iteration of the higher-order calculation at each step, but still requires a couple of repetitions depending on the analysis.

An implementation of k-factor technique in `HERAFitter` is used for the fast approximation of the time-consuming GM-VFN schemes for heavy quarks in DIS. “FAST” heavy-flavour schemes are implemented with k-factors defined as the ratio of calculations at the same perturbative order but for massive vs. massless quarks, e.g. NLO (massive)/NLO (massless). These k-factors are calculated only for the starting PDF and hence, the “FAST” heavy flavour schemes should only be used for quick checks, i.e. full heavy flavour schemes are normally recommended. For the ACOT case, due to long computation time, the k-factors are used in the default settings in HERAFitter.

4.2 *Fast Grid* Techniques

Fast grid techniques exploit the fact that iterative PDF fitting procedures do not impose completely arbitrary changes to the types and shapes of the parameterised functions that represent each PDF. Instead, it can be assumed that a generic PDF can be approximated by a set of interpolating functions with a sufficient number of support points. The accuracy of this approximation can be checked and optimised in various ways with the simplest one being an increase in the number of support points. Having ensured that the approximation bias is negligibly small compared to the experimental and theoretical accuracy for all practical purposes, this method can be used to perform the time consuming higher-order calculations (Eq. 1) only once for the set of interpolating functions. Further iteration of a cross section evaluation for a particular PDF set is fast and implies only sums over the set of interpolators multiplied by factors depending on the PDF. The approach applies equally for the cross sections of processes involving one or two hadrons in the initial state as well as to their renormalisation and factorisation scale variation.

This technique was pioneered in the fastNLO project [77] to facilitate the inclusion of notoriously time consuming jet cross sections at NLO into PDF fits. The APPLGRID [78] project developed an alternative method and, in addition to jets, extended its applicability to other scattering processes, such as DY, heavy quark pair production is association with boson production, etc. While differing in their interpolation and optimisation strategies, both packages construct tables with grids for each bin of an observable in two steps: in the first step, the accessible phase space in the parton momentum fractions x and the renormalisation and factorisation scales $\mu_{\rm R}$ and $\mu_{\rm F}$ is explored in order to optimise the table size. The second step consists of the actual grid filling for the requested observables. Higher-order cross sections can then be restored very efficiently from the pre-produced grids while varying externally provided PDF sets, $\mu_{\rm R}$ and $\mu_{\rm F}$, or the strong coupling $\alpha_s(\mu_R)$. The approach can in principle be extended to arbitrary processes, but requires to establish an interface between the higher-order theory programs and the fast interpolation frameworks. Work in that direction is ongoing for both packages and described in more details in the following:

- The fastNLO project [77] has been interfaced to the NLOJet++ program [68] for the calculation of jet production in DIS [79] as well as 2- and 3-jet production in hadron-hadron collisions at NLO [69, 80]. To demonstrate the applicability to higher-orders, threshold corrections at 2-loop order, which approximate the NNLO for the inclusive jet cross section, have been included into the framework [81] following Ref. [82].

  The latest version of fastNLO convolution program [83] allows for a creation of tables where renormalisation and factorisation scales can be varied as a function of two pre-defined observables, e.g. jet transverse momentum $p_\perp$ and Q for DIS. The fastNLO code is available online [84] where also the jet cross-section grids computed for kinematics of various experiments can be downloaded.

  Dedicated fastNLO libraries and tables with theory predictions for comparison to particular cross section measurements are included into the HERAFitter package. For the HERAFitter implementation, the evaluation of the strong coupling constant is taken consistently with the PDF evolution from the QCDNUM code.
- In the APPLGRID package [78, 85], in addition to the jet cross sections from NLOJet++ in $pp(\bar{p})$ and DIS processes, the calculations of DY production are also implemented. The look-up tables (grids) can be generated with the customised versions of the MCFM parton level DY generator [60–62]. The variation of the renormalisation and factorisation scales is possible a posteriori, when calculating theory predictions with the APPLGRID tables, and independent variation of the strong coupling constant is also allowed. For NNLO predictions in HERAFitter, the k-factors technique can be also applied within the APPLGRID framework.

  The HERAFitter interface to APPLGRID was in particular used by the ATLAS collaboration to extract the strange quark density of the proton from W and Z cross sections [86]. An illustration of ATLAS PDFs extracted employing these techniques is displayed in Fig. 4 together with the comparison to global PDF sets CT10 [17] and NNPDF2.1 [18] (taken from [86]).

5 Fit Methodology

When performing a QCD analysis to determine PDFs there are various assumptions and choices to be made concerning, for example, the functional form of the input parametrisation, the treatment of heavy quarks and their mass values, alternative theoretical calculations, alternative representations of the fit χ^2, different ways of treating correlated systematic uncertainties. It is useful to be able to discriminate or quantify the effect of the chosen ansatz, within a common framework, and HERAFitter is optimally designed for such tests. The methodology employed by HERAFitter relies on a flexible and modular framework that allows for independent integration of the state-of-the-art techniques, either re-

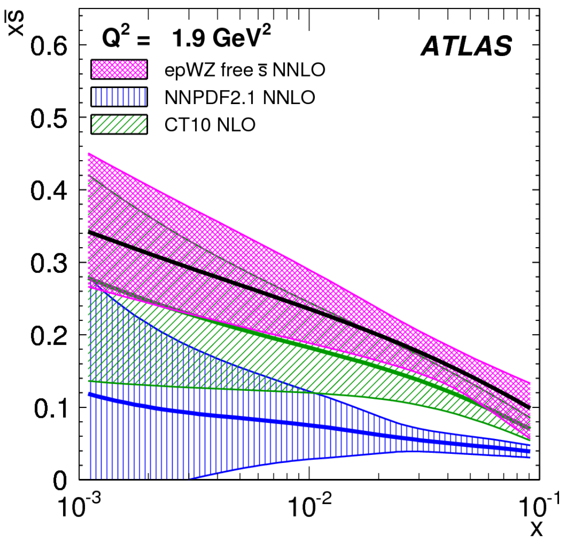

Fig. 4 The strange antiquark density versus x for the ATLAS epWZ free sbar NNLO fit [86] (magenta band) compared to predictions from NNPDF2.1 (blue hatched) and CT10 (green hatched) at $Q^2 = 1.9$ GeV^2. The ATLAS fit was performed using a k-factor approach for NNLO corrections.

lated to the inclusion of a new theoretical calculation, or of new approaches to treat data and their uncertainties.

In this section we describe the available options for the fit methodology in `HERAFitter`. In addition, as an alternative approach to a complete QCD fit, the Bayesian reweighting method, which is also available in `HERAFitter`, is described.

5.1 Functional Forms for PDF Parametrisation

The PDFs can be parametrised using several predefined functional forms and different flavour decompositions:

Standard Polynomials: The standard polynomial form is the most commonly used. A polynomial functional form is used to parametrise the x-dependence of the PDFs, where index j denotes each parametrised PDF flavour:

$$xf_j(x) = A_j x^{B_j}(1-x)^{C_j} P_j(x). \tag{14}$$

The parametrised PDFs are the valence distributions xu_v and xd_v, the gluon distribution xg, and the u-type and d-type sea, $x\bar{U}$, $x\bar{D}$, where $x\bar{U} = x\bar{u}$, $x\bar{D} = x\bar{d} + x\bar{s}$ at the starting scale, which is chosen below the charm mass threshold. The form of polynomials $P_j(x)$ can be varied. The form $(1+\varepsilon_j\sqrt{x}+D_j x+E_j x^2)$ is used for the HERAPDF [40] with additional constraints relating to the flavour decomposition of the light sea. This parametrization is termed HERAPDF-style. The polynomial can also be parametrized in the CTEQ-style, $P_i(x)$ takes the form $e^{a_3 x}(1+e^{a_4}x+e^{a_5}x^2)$ and, in contrast to the HERAPDF-style, this is positive by construction. QCD number and momentum sum rules are used to determine the normalisations A for the valence and gluon distributions, and the sum-rule integrals are solved analytically.

Bi-Log-Normal Distributions: This parametrisation is motivated by multi-particle statistics and has the following functional form:

$$xf_j(x) = a_j x^{p_j - b_j \log(x)}(1-x)^{q_j - d_j \log(1-x)}. \tag{15}$$

This function can be regarded as a generalisation of the standard polynomial form described above, however, numerical integration of Eq. 15 is required in order to satisfy the QCD sum rules.

Chebyshev Polynomials: A flexible parametrisation based on the Chebyshev polynomials can be employed for the gluon and sea distributions. Polynomials with argument $\log(x)$ are considered .or better modelling the low-x asymptotic of those PDFs. The polynomials are multiplied by a factor of $(1-x)$ to ensure that they vanish as $x \to 1$. The resulting parametric form reads

$$xg(x) = A_g(1-x)\sum_{i=0}^{N_g-1} A_{g_i} T_i\left(-\frac{2\log x - \log x_{\min}}{\log x_{\min}}\right), \tag{16}$$

$$xS(x) = (1-x)\sum_{i=0}^{N_S-1} A_{S_i} T_i\left(-\frac{2\log x - \log x_{\min}}{\log x_{\min}}\right), \tag{17}$$

where T_i are first-type Chebyshev polynomials of order i. The normalisation factor A_g is derived from the momentum sum rule analytically. Values of $N_{g,S}$ to 15 are allowed, however the fit quality is already similar to that of the standard-polynomial parametrisation from $N_{g,S} \geq 5$ and has a similar number of free parameters. Fig. 5 (taken from [87]) shows a comparison of the gluon density obtained with the parametrisation Eqs. 16, 17 to the standard-polynomial one, for $N_{g,S} = 9$.

External PDFs: `HERAFitter` also provides the possibility to access external PDF sets, which can be used to compute theoretical predictions for the cross sections for all the processes available in `HERAFitter`. This is possible via an interface to `LHAPDF` [37, 38] providing access to the global PDF sets. `HERAFitter` also allows to evolve PDFs from `LHAPDF` with `QCDNUM` using the corresponding grids as a starting scale. Fig. 6 illustrates a comparison of various PDFs accessed from `LHAPDF` as produced with the drawing tools available in `HERAFitter`.

5.2 Representation of χ^2

The PDF parameters are determined in `HERAFitter` by minimisation of the χ^2 function taking into account correlated

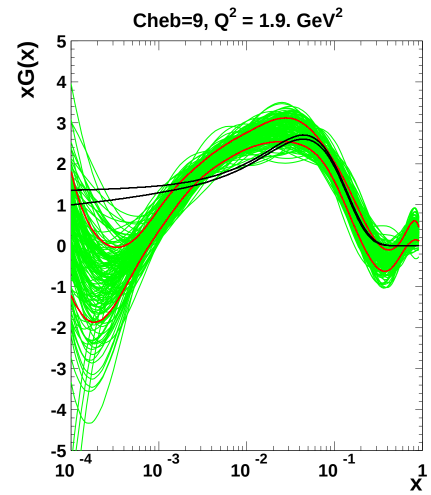

Fig. 5 The gluon density is shown at the starting scale. The black lines correspond to the uncertainty band of the gluon distribution using a standard parametrisation and it is compared to the case of the Chebyshev parametrisation [87]. The uncertainty band for the latter case is estimated using the Monte Carlo technique **??** with the green lines denoting fits to data replica. Red lines indicate the standard deviation about the mean value of these replicas.

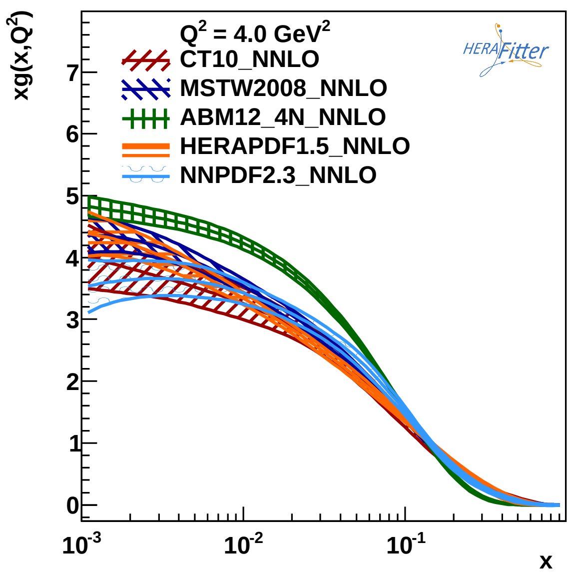

Fig. 6 The gluon PDF as extracted by various PDF groups at the scale of $Q^2 = 4$ GeV^2, plotted using the drawing tools from `HERAFitter`.

and uncorrelated measurement uncertainties. There are various forms of the χ^2 e.g. using a covariance matrix or providing nuisance parameters to encode the dependence of each correlated systematic uncertainty for each measured data point. The options available in `HERAFitter` are following.

Covariance Matrix Representation: For a data point μ_i with a corresponding theory prediction m_i, the χ^2 function can be expressed in the following form:

$$\chi^2(m) = \sum_{i,k}(m_i - \mu_i)C^{-1}_{ik}(m_k - \mu_k), \tag{18}$$

where the experimental uncertainties are given as a covariance matrix $C_{i,k}$ for measurements in bins i and k. The covariance matrix C_{ik} is given by a sum of statistical, uncorrelated and correlated systematic contributions:

$$C_{ik} = C^{stat}_{ik} + C^{uncor}_{ik} + C^{sys}_{ik}. \tag{19}$$

Using this representation one cannot distinguish the separate effect of each source of systematic uncertainty.

Nuisance Parameters Representation: In this case the χ^2 form is expressed as

$$\chi^2(m,b) = \sum_i \frac{\left[\mu_i - m_i\left(1 - \sum_j \gamma^i_j b_j\right)\right]^2}{\delta^2_{i,\mathrm{unc}} m_i^2 + \delta^2_{i,\mathrm{stat}}\,\mu_i m_i \left(1 - \sum_j \gamma^i_j b_j\right)} + \sum_j b_j^2, \tag{20}$$

where, $\delta_{i,\mathrm{stat}}$ and $\delta_{i,\mathrm{unc}}$ are relative statistical and uncorrelated systematic uncertainties of the measurement i. Further, γ^i_j quantifies the sensitivity of the measurement to the correlated systematic source j. The function χ^2 depends in addition on the set of systematic nuisance parameters b_j. This definition of the χ^2 function assumes that systematic uncertainties are proportional to the central prediction values (multiplicative errors), whereas the statistical uncertainties scale with the square root of the expected number of events.

During the χ^2 minimisation, the nuisance parameters b_j and the PDFs are determined, such that the effect of different sources of systematic uncertainties can be distinguished.

Mixed Form Representation: In some cases, the statistical and systematic uncertainties of experimental data are provided in different forms. For example, the correlated experimental systematic uncertainties are available as nuisance parameters but the bin-to-bin statistical correlations are given in the form of covariance matrix. `HERAFitter` offers the possibilitiy to include such mixed forms of information. form of treating statistical, uncorrelated and correlated systematic uncertainties.

Any source of measured systematic uncertainty can be treated as additive or multiplicative. The statistical uncertainties can be included as additive or Poisson. Minimisation with respect to nuisance parameters is performed analytically, however for more detailed studies of correlations individual nuisance parameters can be included in the `MINUIT` minimisation.

5.3 Treatment of the Experimental Uncertainties

Three distinct methods for propagating experimental uncertainties to PDFs are implemented in `HERAFitter` and reviewed here: the Hessian, Offset, and Monte Carlo method.

Hessian (Eigenvector) method: The PDF uncertainties reflecting the uncertainties in experimental data are estimated by examining the shape of χ^2 in the neighbourhood of the minimum [88]. Following approach of Ref. [88], the Hessian matrix is defined by the second derivatives of χ^2 on the fitted PDF parameters. The matrix is diagonalised and the Hessian eigenvectors are computed. Due to orthogonality, these vectors correspond to independent sources of uncertainty in the obtained PDFs.

Offset method: The Offset method [89] uses the χ^2 function for the central fit, however only uncorrelated uncertainties are taken into account. The goodness of the fit can no longer be judged from the χ^2 since correlated uncertainties are ignored. The correlated uncertainties are propagated into the PDF uncertainties by performing variants of the fit with the experimental data varied by $\pm 1\sigma$ from the central value for each systematic source. The resulting deviations of the PDF parameters from the ones obtained in the central fit are statistically independent, and they can be combined in quadrature to arrive at the total PDF systematic uncertainty.
The uncertainties estimated by the offset method are generally larger than those from the Hessian method.

Monte Carlo method: The Monte-Carlo technique [90, 91] can also be used to determine PDF uncertainties. The uncertainties are estimated using pseudo-data replicas (typically > 100) randomly generated from the measurement central values and their systematic and statistical uncertainties taking into account all point-to-point correlations. The QCD fit is performed for each replica and the PDF central values and their experimental uncertainties are estimated from the distribution of the PDF parameters obtained in these fits, by taking the mean values and standard deviations over the replicas.
The MC method has been checked against the standard error estimation of the PDF uncertainties obtained by the Hessian method. A good agreement was found between the methods provided that Gaussian distributions of statistical and systematic uncertainties are assumed in the MC approach [36]. A comparison is illustrated in Fig. 7. Similar findings were reported by the MSTW global analysis [92].
Since the MC method requires large number of replicas, the eigenvector representation is a more convenient way to store the PDF uncertainties. It is possible to transform MC to eigenvector representation as shown by [93]. Tools to perform this transformation are provided with `HERAFitter` and were recently employed for the representation of correlated sets of PDFs at different perturbative order [94].

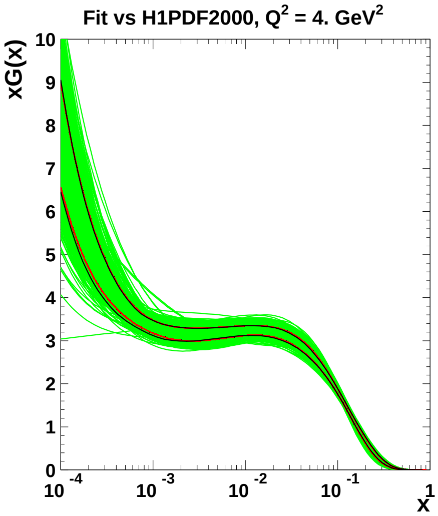

Fig. 7 Comparison between the standard error calculations as employed by the Hessian approach (black lines) and the MC approach (with more than 100 replicas) assuming Gaussian distribution for uncertainty distributions, shown here for each replica (green lines) together with the evaluated standard deviation (red lines) [36]. The black lines in the figure are difficult to see because agreement of the methods is so good that thet are mostly covered by the red lines.

The nuisance parameter representation of χ^2 in Eq. 20 is derived assuming symmetric experimental errors, however, the published systematic uncertainties are often asymmetric. `HERAFitter` provides the possibility to use asymmetric systematic uncertainties. The implementation relies on the assumption that asymmetric uncertainties can be described by a parabolic function. The nuisance parameter in Eq. 20 is modified as follows

$$\gamma^i_j \to \omega^i_j b_j + \gamma^i_j, \tag{21}$$

where the coefficients ω^i_j, γ^i_j are defined from the maximum and minimum shifts of the cross sections due to variaion of the systematic uncertainty j, $S^{\pm}_{ij}$,

$$\omega^i_j = \frac{1}{2}\left(S^+_{ij} + S^-_{ij}\right), \qquad \gamma^i_j = \frac{1}{2}\left(S^+_{ij} - S^-_{ij}\right). \tag{22}$$

5.4 Treatment of the Theoretical Input Parameters

The results of a QCD fit depend not only on the input data but also on the input parameters used in the theoretical calculations. Nowadays, PDF groups address the impact of the choices of theoretical parameters by providing alternative PDFs with different choices of the mass of the charm quarks, m_c, mass of the bottom quarks, m_b, and the value of $\alpha_s(M_Z)$.

Other important aspects are the choice of the functional form for the PDFs at the starting scale and the value of the starting scale itself. HERAFitter provides the possibility of different user choices of all these inputs to the theory.

5.5 Bayesian Reweighting Techniques

As an alternative to performing a full QCD fit, HERAFitter allows the user to assess the impact of including new data in an existing fit using the Bayesian Reweighting technique. The method provides a fast estimate of the impact of new data on PDFs. Bayesian Reweighting was first proposed for PDF sets delivered in the form of MC replicas by [90] and further developed by the NNPDF Collaboration [95, 96]. More recently, a method to perform Bayesian Reweighting studies starting from PDF fits for which uncertainties are provided in the eigenvectors representation has been also developed [92]. The latter is based on generating replica sets by introducing Gaussian fluctuations on the central PDF set with a variance determined by the PDF uncertainty given by the eigenvectors. Both reweighting methods are implemented in HERAFitter.

The Bayesian Reweighting technique relies on the fact that MC replicas of a PDF set give a representation of the probability distribution in the space of PDFs. In particular, the PDFs are represented as ensembles of N_{rep} equiprobable (*i.e.* having all weight equal to unity) replicas, $\{f\}$. The central value for a given observable, $\mathcal{O}(\{f\})$, is computed as the average of the predictions obtained from the ensemble as

$$\langle \mathcal{O}(\{f\}) \rangle = \frac{1}{N_{\mathrm{rep}}} \sum_{k=1}^{N_{\mathrm{rep}}} \mathcal{O}(f^k), \tag{23}$$

and the uncertainty as the standard deviation of the sample.

Upon inclusion of new data the prior probability distribution, given by the prior PDF set, is updated according to Bayes Theorem and the weight of each replica, w_k, is updated according to

$$w_k = \frac{(\chi_k^2)^{\frac{1}{2}(N_{\mathrm{data}}-1)} e^{-\frac{1}{2}\chi_k^2}}{\frac{1}{N_{\mathrm{rep}}} \sum_{k=1}^{N_{\mathrm{rep}}} (\chi_k^2)^{\frac{1}{2}(N_{\mathrm{data}}-1)} e^{-\frac{1}{2}\chi_k^2}}, \tag{24}$$

where N_{data} is the number of new data points, k denotes the specific replica for which the weight is calculated and χ_k^2 is the chi-square of the new data obtained using the k-th PDF replica. Given a PDF set and a corresponding set of weights, which describes the impact of the inclusion of new data, the prediction for a given observable after inclusion of the new data can be computed as the *weighted* average,

$$\langle \mathcal{O}(\{f\}) \rangle = \frac{1}{N_{\mathrm{rep}}} \sum_{k=1}^{N_{\mathrm{rep}}} w_k \mathcal{O}(f^k). \tag{25}$$

To simplify the use of reweighted set, an unweighted set (*i.e.* a set of equiprobable replicas which incorporates the information contained in the weights) is generated according to the unweighting procedure described in [95]. The number of effective replicas of a reweighted set is measured by its Shannon Entropy [96]

$$N_{\mathrm{eff}} \equiv \exp\left\{ \frac{1}{N_{\mathrm{rep}}} \sum_{k=1}^{N_{\mathrm{rep}}} w_k \ln(N_{\mathrm{rep}}/w_k) \right\}, \tag{26}$$

which corresponds to the size of a refitted equiprobable replica set containing the same amount of information. This number of effective replicas, N_{eff}, gives an indicative measure of the optimal size of an unweighted replica set produced using the reweighting/unweighting procedure. No extra information is gained by producing a final unweighted set that has a number of replicas (significantly) larger than N_{eff}. Clearly if N_{eff} is much smaller than the original number of replicas the new data have great impact, but it is unreliable to use the new reweghted set. Instead a full refit should be performed.

6 Alternatives to DGLAP Formalism

The QCD calculations based on the DGLAP [21–25] evolution equations are very successful in describing all relevant hard scattering data in the perturbative region $Q^2 \gtrsim 1\,\mathrm{GeV}^2$. At small-$x$ and small-Q^2 the DGLAP dynamics may be modified by non-perturbative QCD effects like saturation-based dipole models and other higher twist effects. Different approaches that are alternatives to the DGLAP formalism can be used to analyse DIS data in HERAFitter. These include several different dipole models and the use of transverse momentum dependent, or unintegrated PDFs (uPDFs).

6.1 Dipole Models

The dipole picture provides an alternative approach to the proton-virtual photon scattering at low x providing the description of both inclusive and diffractive processes. In this approach, the virtual photon fluctuates into a $q\bar{q}$ (or $q\bar{q}g$) dipole which interacts with the proton [97]. The dipoles can be considered as quasi-stable quantum mechanical states, which have very long life time $\propto 1/m_p x$ and a size which is not changed by scattering. The dynamics of the interaction are embedded in the dipole scattering amplitude.

Several dipole models which assume different behaviour of the dipole-proton cross sections are implemented in HERAFitter: the Golec-Biernat-Wüsthoff (GBW) dipole saturation model [32], the colour glass condensate approach to the high parton density regime called the Iancu-Itakura-Munier (IIM) dipole model [33] and a modified GBW model which takes into account the effects of DGLAP evolution called the Bartels-Golec-Kowalski (BGK) dipole model [34].

GBW model: In the GBW model the dipole-proton cross section σ_{dip} is given by

$$\sigma_{\mathrm{dip}}(x,r^2) = \sigma_0 \left(1 - \exp\left[-\frac{r^2}{4R_0^2(x)}\right]\right), \quad (27)$$

where r corresponds to the transverse separation between the quark and the antiquark, and R_0^2 is an x-dependent scale parameter which represents the spacing of the gluons in the proton. $R_0^2(x) = (x/x_0)^{\lambda} 1/\mathrm{GeV}^2$ is called the saturation radius. The cross-section normalisation σ_0, x_0, and λ are parameters of the model commonly fitted to the DIS data. This model gives exact Bjorken scaling when the dipole size r is small.

IIM model: The IIM model assumes an improved expression for the dipole cross section which is based on the Balitsky-Kovchegov equation [98]. The explicit formula for σ_{dip} can be found in [33]. The alternative scale parameter $\tilde{R}$, x_0 and λ are fitted parameters of the model.

BGK model: The BGK model is a modification of the GBW model assuming that the spacing R_0 is inverse of the gluon density and taking into account the DGLAP evolution of the latter. The gluon density parametrised at some starting scale by Eq. 14 is evolved to larger scales using DGLAP evolution.

BGK model with valence quarks: The dipole models are valid in the low-x region only, where the valence quark contribution to the total proton momentum is 5% to 15% for x from 0.0001 to 0.01 [99]. The new HERA F_2 measurements have a precision which is better than 2%. Therefore, in `HERAFitter` the contribution of the valence quarks can be taken into account in the original BGK model [100].

6.2 Transverse Momentum Dependent PDFs

QCD calculations of multiple-scale processes and complex final-states require in general transverse-momentum dependent (TMD) [13], or unintegrated, parton distribution and parton decay functions [101–109]. The TMD factorisation has been proven recently [13] for inclusive DIS. For particular hadron-hadron scattering processes, like heavy flavor, vector boson and Higgs production, TMD factorisation has also been proven in the high-energy (small-x) limit [110–112].

In the framework of high-energy factorisation [110, 113, 114] the DIS cross section can be written as a convolution in both longitudinal and transverse momenta of the TMD parton density function $\mathscr{A}(x,k_t,\mu)$ with the off-shell partonic matrix elements, as follows

$$\sigma_j(x,Q^2) = \int_x^1 dz \int d^2k_t \; \hat{\sigma}_j(x,Q^2,z,k_t) \; \mathscr{A}\left(z,k_t,\mu_F^2\right) \quad (28)$$

with the DIS cross sections σ_j, ($j = 2, L$) related to the structure functions F_2 and F_L. The hard-scattering kernels $\hat{\sigma}_j$ of Eq. 28, are k_t-dependent and the evolution of the transverse-momentum dependent gluon density $\mathscr{A}$ is obtained by combining the resummation of small-x logarithmic contributions [115–117] with medium-x and large-x contributions to parton splitting [21, 24, 25] according to the CCFM evolution equation [29, 118, 119].

The factorisation formula (28) allows resummation of logarithmically enhanced small-x contributions to all orders in perturbation theory, both in the hard scattering coefficients and in the parton evolution, fully taking into account the dependence on the factorisation scale μ_F and on the factorisation scheme [120, 121].

The cross section σ_j, ($j = 2, L$) is calculated in a FFN scheme, where only the boson-gluon fusion process ($\gamma^* g^* \to q\bar{q}$) is included. The masses of the quarks are explicitly included as parameters of the model. In addition to $\gamma^* g^* \to q\bar{q}$, the contribution from valence quarks is included via $\gamma^* q \to q$ by using a CCFM evolution of valence quarks [122, 123].

CCFM Grid Techniques: The CCFM evolution cannot be written easily in an analytic closed form. For this reason a Monte Carlo method is employed, which is however time-consuming, and cannot be used in a straightforward manner in a fit program.

Following the convolution method introduced in [123, 124], the kernel $\tilde{\mathscr{A}}(x'',k_t,p)$ is determined from the Monte Carlo solution of the CCFM evolution equation, and then folded with the non-perturbative starting distribution $\mathscr{A}_0(x)$

$$\begin{aligned} x\mathscr{A}(x,k_t,p) &= x\int dx' \int dx'' \mathscr{A}_0(x') \tilde{\mathscr{A}}\left(x'',k_t,p\right) \delta(x'x''-x) \\ &= \int dx' \mathscr{A}_0(x') \cdot \frac{x}{x'} \; \tilde{\mathscr{A}}\left(\frac{x}{x'},k_t,p\right), \end{aligned} \quad (29)$$

where k_t denotes the transverse momentum of the propagator gluon and p is the evolution variable.

The kernel $\tilde{\mathscr{A}}$ incorporates all of the dynamics of the evolution. It is defined on a grid of $50 \otimes 50 \otimes 50$ bins in x, k_t, p. The binning in the grid is logarithmic, except for the longitudinal variable x where 40 bins in logarithmic spacing below 0.1, and 10 bins in linear spacing above 0.1 are used.

Calculation of the cross section according to Eq. 28 involves a multidimensional Monte Carlo integration which is time consuming and suffers from numerical fluctuations. This cannot be employed directly in a fit procedure involving the calculation of numerical derivatives in the search for the minimum. Instead the following equation is applied:

$$\begin{aligned} \sigma(x,Q^2) &= \int_x^1 dx_g \mathscr{A}(x_g,k_t,p) \hat{\sigma}(x,x_g,Q^2), \\ &= \int_x^1 dx' \mathscr{A}_0(x') \cdot \tilde{\sigma}(x/x',Q^2), \end{aligned} \quad (30)$$

where first $\tilde{\sigma}(x',Q^2)$ is calculated numerically with a Monte Carlo integration on a grid in x for the values of Q^2 used in the fit. Then the last step in Eq. 30 is performed with a fast numerical gauss integration, which can be used in standard fit procedures.

Functional Forms for TMD parametrisation: For the starting distribution $\mathscr{A}_0$, at the starting scale Q_0^2, the following form is used:

$$x\mathscr{A}_0(x,k_t) = Nx^{-B}(1-x)^C\left(1 - Dx + E\sqrt{x}\right)\exp[-k_t^2/\sigma^2] \quad (31)$$

with $\sigma^2 = Q_0^2/2$ and the free parameters N, B, C, D, E. Valence quarks are treated using the method of Ref. [122] as described in Ref. [123] with a starting distribution taken from any collinear PDF and imposing the flavor sum rule at every scale p.
The TMD parton densities can be plotted either with `HERAFitter` provided tools or with `TMDplotter` [39].

7 `HERAFitter` Code Organisation

`HERAFitter` is an open source code and it can be downloaded from the dedicated webpage [1] together with its supporting documentation and *fast grid* theory files (described in section 4) associated with the properly formatted data files. The source code contains all the relevant information to perform QCD fits with HERA DIS data as a default set [1]. The performance time depends on the fitting options and varies from 10 minutes (using "FAST" techniques as described in section 4) to several hours when full uncertainties are estimated. The `HERAFitter` code is a combination of `C++` and `Fortran 77` libraries with minimal dependencies, i.e. for the default fitting options no external dependencies are required except `QCDNUM` evolution program [26] and CERN libraries. The `ROOT` libraries are only required for the drawing tools and when invoking `APPLGRID`. Drawing tool inbuilt in `HERAFitter` provides a qualitative and quantitative assessment of the results. Fig. 8 shows an illustration of a comparison between the inclusive NC data from the HERA I with the predictions based on HERAPDF1.0 PDFs. The consistency of the measurements and the theory is expressed by pulls, defined as a difference between data and theory divided by the uncorrelated error of the data. In each kinematic bin of the measurement, pulls are provided in units of standard deviation (sigma).

In `HERAFitter` there are also available cache options, fast evolution kernels, and the OpenMP (Open Multi-Processing) interface which allows parallel applications of the GM-VFNS theory predictions in DIS. In addition, the `HERAFitter` references and GNU public licence are provided together with the main source code.

[1]Default settings in `HERAFitter` are tuned to reproduce the central HERAPDF1.0 set.

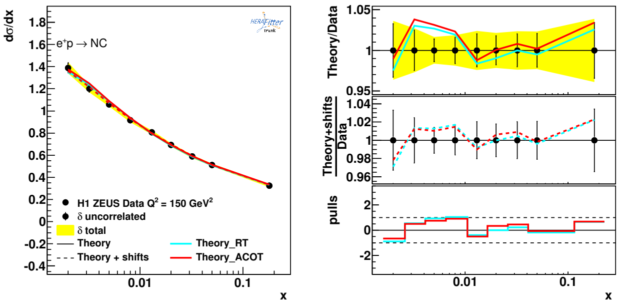

Fig. 8 An illustration of the consistency of HERA measurements [40] and the theory predictions, obtained in `HERAFitter` with the default drawing tool.

8 Applications of `HERAFitter`

The `HERAFitter` program was used in a number of experimental and theoretical analyses. This list includes several LHC analyses of SM processes, namely inclusive Drell-Yan and W and Z production [86, 125–128], inclusive jet production [129]. The results of QCD analyses using `HERAFitter` were also published by HERA experiments in the inclusive [40, 130] and the heavy flavour production measurements [131, 132]. Following theory and phenomenology studies were performed with `HERAFitter`: a determination of the transverse momentum dependent gluon density using precision HERA data [123], an analysis of HERA data within a dipole model [100], the study of the low-x uncertainties in PDFs determined from the HERA data using different parametrisations [87] and the impact of QED radiative corrections on PDFs [133]. A recent study based on a set of PDFs determined with the `HERAFitter` and addressing the correlated uncertainties between orders was published in [94].

The `HERAFitter` framework has been used to produce PDF grids from the QCD analyses performed at HERA [40, 134] and at the LHC [135], using measurements from ATLAS [86, 129], which can be used to study predictions for SM or beyond SM processes. Moreover, `HERAFitter` provides a possibility to perform various benchmarking exercises [136] and impact studies for possible future colliders as demonstrated by the QCD studies at the LHeC [137].

9 Summary

`HERAFitter` is an open-source platform designed to study the structure of the proton. It provides unique and flexible framework with a wide variety of QCD tools to facilitate analyses of the experimental data and theoretical calculations. `HERAFitter` allows for direct comparisons of various theoretical approaches under the same settings, different methodologies in treating the experimental and model uncertainties and can be used for benchmarking studies. The growth of `HERAFitter` is driven by the latest QCD advances in theoretical calculations and in precision of experimental data.

Acknowledgements `HERAFitter` developers team acknowledges the kind hospitality of DESY and funding by the Helmholtz Alliance "Physics at the Terascale" of the Helmholtz Association. We are grateful to the DESY IT department for their support of the `HERAFitter` developers. Additional support was received from the BMBF-JINR cooperation program, the Heisenberg-Landau program, the RFBR grant 12-02-91526-CERN a, the Polish NSC project DEC-2011/03/B/ST2/00220 and a dedicated funding of the Initiative and Networking Fond of Helmholtz Association SO-072. We also acknowledge Nathan Hartland with Luigi Del Debbio for contributing to the implementation of the Bayesian Reweighting technique and would like to thank R. Thorne for fruitful discussions.
