	9	Summary			

70 proton collisions demand high-precision calculations and com-71 putations to test the validity of the Standard Model (SM) and 72 factorisation in Quantum Chromodynamics (QCD). Using 73 collinear factorisation, hadron inclusive cross sections may ₇₄ be written as

$$\sigma(\alpha_{s}(\mu_{R}^{2}), \mu_{R}^{2}, \mu_{F}^{2}) = \sum_{a,b} \int_{0}^{1} dx_{1} dx_{2} f_{a}(x_{1}, \mu_{F}^{2}) f_{b}(x_{2}, \mu_{F}^{2}) \times \hat{\sigma}^{ab}(x_{1}, x_{2}; \alpha_{s}(\mu_{R}^{2}), \mu_{R}^{2}, \mu_{F}^{2}),$$
(1)

where the cross section σ is expressed as a convolution of Parton Distribution Functions (PDFs) f_a and f_b with the parton cross section $\hat{\sigma}^{ab}$. At Leading-Order (LO), the PDFs represent the probability of finding a specific parton a(b)in the first (second) proton carrying a fraction x_1 (x_2) of its momentum. The indices a and b in the Eq. 1 indicate the various kinds of partons, i.e. gluons, quarks and antiquarks 82 of different flavours, that are considered as the constituents $_{83}$ of the proton. The PDFs depend on factorisation scale, $\mu_{\rm F}$, 84 while the parton cross sections depend on the strong cou- $\alpha_{\rm s}$ pling, $\alpha_{\rm s}$, and the factorisation and renormalisation scales, \mathfrak{F}_{B} \mathfrak{g}_{B} and \mathfrak{g}_{B} . The parton cross sections $\hat{\sigma}^{ab}$ are calculable in pQCD whereas PDFs are non-perturbative and are thus con-88 strained by global fits to a variety of experimental data. The 89 assumption that PDFs are universal, within a particular fac-₉₀ torisation scheme [9–13], is crucial to this procedure. Recent review articles on PDFs can be found in Refs. [14, 15].

Accurate determination of PDFs as a function of x reguires large amount of hard-process experimental data, cov-94 ering a wide kinematic region and sensitive to different kinds 95 of partons. Measurements of the inclusive Neutral Current 96 (NC) and Charge Current (CC) Deep Inelastic Scattering 97 (DIS) at the *ep* collider HERA provide crucial information ₉₈ for determining the PDFs. Hard processes in pp and $p\bar{p}$ col-99 lisions at the LHC and the Tevatron, respectively, provide 100 complementary information to the DIS measurements. The PDFs are determined from χ^2 fits of the theoretical predic-11 102 tions to the data [16–20]. The rapid flow of new data from 11 103 the LHC experiments and the corresponding theoretical developments, which are providing predictions for more com-105 plex processes at increasingly higher orders, has motivated $\frac{12}{13}$ the development of a tool to combine them together in a fast, 13 107 efficient, open-source platform.

This paper describes the open-source QCD fit platform 13 109 HERAFitter which includes a set of tools designed to facilitate comprehensive global QCD analyses of pp, $p\bar{p}$ and epscattering data. It has been developed for the determination $\frac{1}{14}$ $\frac{1}{12}$ of PDFs and the extraction of fundamental QCD parameters 14 113 such as the heavy quark masses and the strong coupling con-14 114 stant. It also provides a common platform for comparison of different theoretical approaches. Furthermore, it can be used for direct tests of the impact of new experimental data on the PDFs and on the SM parameters.

This paper is organised as follows. The structure and overview of HERAFitter are presented in Section 2. In Section 3 the various processes available in HERAFitter and the corresponding theoretical calculations, performed within the framework of collinear factorisation and the DGLAP [21– 25] formalism, are discussed. In Section 4 tools for fast calculations of the theoretical predictions used in HERAFitter are presented. In Section 5 the methodology of determining PDFs through fits based on various χ^2 definitions is explained. In particular, different treatment of correlated experimental uncertainties are presented. Alternative approaches to the DGLAP formalism are presented in Section 6. The HERAFitter code organisation is discussed in Section 7, specific applications of the package are given in Section 8 and a summary is presented in Section 9.

2 The HERAFitter Structure

119

In this section the functionality of HERAFitter is described. A block diagram in Fig 1 gives a schematic view of the HERAFitter functionality which can be divided into four main blocks:

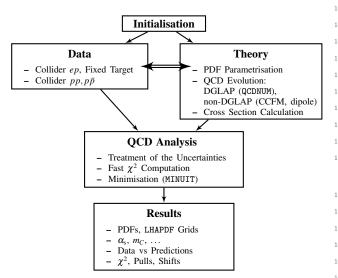

Fig. 1 Schematic structure of the HERAFitter program.

Data: Different measurements from various processes are implemented in the HERAFitter package including the full ties. HERA inclusive scattering data are sensitive to quark PDFs and to gluon PDFs through scaling violations and the longitudinal structure function F_L . These data are the back- 170 QCD analysis: The PDFs are determined by a least square

Experimental Data	Process	Reaction	Theory calculations, schemes
HERA, Fixed Target	DIS NC	$ep \rightarrow eX$	TR', ACOT, ZM (QCDNUM), FFN (DPENQCDRAD, QCDNUM), TMD (uPDFevolv)
HERA	DIS CC	$ep ightarrow v_e X$	ACOT, ZM (QCDNUM), FFN (OPENQCDRAD)
	DIS jets	$ep \rightarrow e \text{ jets}X$	NLOJet++ (fastNLO)

Table 1 The list of experimental data and theory calculations implemented in the HERAFitter package. The references for the individual calculations and schemes are given in the text.

PDF groups [16–20]. They can be supplemented by HERA measurements sensitive to heavy quarks and by HERA jet measurements, which have sensitivity to the gluon PDF. However, the kinematic range of HERA data mostly covers low and medium x ranges. Improvements in precision of PDFs require additional constraints on the gluon and quark distributions at high-x, better understanding of heavy quark distributions and decomposition of the light-quark sea. For these purposes, measurements from the fixed-target experiments, 154 the Tevatron and the LHC can be used. The processes that are currently available in HERAFitter framework are listed 156 in Tab. 1.

157 Theory: The PDFs are parametrised at a starting input scale Q_0^2 by a chosen functional form with a set of free parameters **p**. These PDFs are evolved to the scale of the measurement Q^2 , $Q^2 > Q_0^2$. The evolution uses the DGLAP formalism [21-25] (as implemented in QCDNUM [26]) by default, however CCFM evolution [27–30] is also available (as implemented in uPDFevolv [31]). The prediction of the cross section for a particular process is obtained, assuming factorisation, by the convolution of the evolved PDFs and the appropriate hard-process parton scattering cross section. Appropriate theory calculations are listed in Tab. 1. Alternainformation on their uncorrelated and correlated uncertain- 168 tively, predictions using dipole models [32-34] can also be

bone of any proton PDF extraction, and are used by all global 171 fit, minimising a χ^2 function, constructed using the input

data and theory predictions, with the MINUIT [35] program. In HERAFitter various choices are available to account for the experimental uncertainties. Correlated experimental uncertainties can be accounted for using a nuisance parameter method or a covariance matrix method as described in sec- $_{197}$ where the functions P_{ab} are the evolution kernels or splitting tion 5.2. Different statistical assumptions for the distributions of the systematic uncertainties, like Gaussian or Log-Normal [36] can also be studied (see section 5.3).

Results: The resulting PDFs are provided in a format ready to be used by the LHAPDF library [37, 38] or by TMDlib [39]. HERAFitter drawing tools can be used to display the PDFs with their uncertainties at a chosen scale. As an example, the first set of PDFs extracted using HERAFitter from HERA I data, HERAPDF1.0 [40], is shown in Fig. 2 (taken from [40]). Note that the PDFs displayed are parton momentum distributions $xf(x,\mu_E^2)$ since this is how PDFs are conventionally stored and displayed.

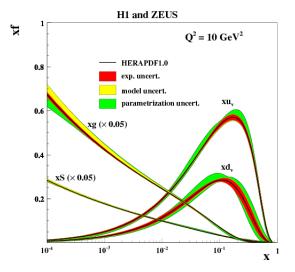

Fig. 2 Distributions of valence (xu_v, xd_v) , sea (xS) and the gluon (g)densities in HERAPDF1.0 [40]. The gluon and the sea distributions are scaled down by a factor of 20. The experimental, model and parametrisation uncertainties are shown as coloured bands

3 Theoretical formalism using DGLAP evolution

[21–25] evolution is described.

dependence or "evolution" of the PDFs can be predicted by 235 the renormalisation group equations. By requiring that phys- $_{236}$ is related to their difference, $xF_3 \approx x \sum 2e_q a_q (q-\overline{q})$ (where ical observables are independent of μ_F , a representation of 237 a_q is the axial-vector quark coupling and e_q the quark elecparton evolution in terms of the DGLAP equations:

$$\frac{d f_a(x, \mu_F^2)}{d \log \mu_F^2} = \sum_{b=a\bar{a}, e} \int_x^1 \frac{dz}{z} P_{ab} \left(\frac{x}{z}; \mu_F^2\right) f_b(z, \mu_F^2), \tag{2}$$

¹⁹⁸ functions, which represent the probability of finding parton a in parton b. They can be calculated as a perturbative expansion in α_s . Once PDFs are determined at the initial scale Q_0^2 , their evolution to any other scale $Q^2 > Q_0^2$ is entirely deter-202 mined by the DGLAP equations. The PDFs are then used to calculate cross sections for various different processes. Alternative approaches to DGLAP evolution, valid in different 205 kinematic regimes, are also implemented in HERAFitter and will be discussed in the next sections.

207 3.1 Deep Inelastic Scattering and Proton Structure

208 The formalism that relates the DIS measurements to pQCD and the PDFs has been described in detail in many extensive reviews (see e.g. Ref. [41]) and it is only briefly summarised here. DIS is the process where a lepton scatters off the partons in the proton by a virtual exchange of a NC (neutral current) or CC (charged current) vector boson and, as a result, a scattered lepton and a multi-hadronic final state are produced. The common DIS kinematic variables are the scale of the process Q^2 , the absolute squared four-momentum of the exchange boson, Bjorken x, which can be related in the parton model to the fraction of momentum carried by the struck quark, and the inelasticity y. These are related by $y = Q^2/sx$, where s is the squared centre-of-mass (c.o.m.) energy.

The NC cross section can be expressed in terms of generalised structure functions:

$$\frac{d^2\sigma_{NC}^{e^{\pm}p}}{dxdQ^2} = \frac{2\pi\alpha^2}{xQ^4} \cdot \sigma_{r,NC}^{e^{\pm}p},\tag{3}$$

$$\sigma_{r,NC}^{e^{\pm}p} = Y_{+}\tilde{F}_{2}^{\pm} \mp Y_{-}x\tilde{F}_{3}^{\pm} - y^{2}\tilde{F}_{L}^{\pm}, \tag{4}$$

where $Y_{\pm} = 1 \pm (1 - y)^2$ and the electromagnetic coupling constant α , the photon propagator and a helicity factor are absorbed in the definition of the reduced cross section σ_r . The generalised structure functions \tilde{F} can be written as linear combinations of the proton structure functions F^{γ} , $F^{\gamma Z}$ and F^{Z} , which are associated to pure photon exchange terms, photon-Z interference terms and pure Z exchange terms, respectively. The structure function \tilde{F}_2 is the dominant contribution to the cross section, $x\tilde{F}_3$ becomes important at high In this section the theoretical formalism based on DGLAP $_{232}$ Q^2 and \tilde{F}_L is sizable only at high y. In the framework of pQCD the structure functions are directly related to the PDFs. A direct consequence of factorisation (Eq. 1) is that scale 234 i.e. in leading order (LO) F_2 is the weighted momentum sum of quark and anti-quark distributions, $F_2 \approx x \sum e_q^2 (q + \overline{q}), xF_3$ $_{238}$ tric charge) and F_L vanishes. At higher orders, terms related

to the gluon density distribution ($\alpha_s g$) appear, in particular 282 OPENQCDRAD [42], as implemented by the ABM group. This F_L is strongly related to the low-x gluon.

case, can be expressed in terms of another set of structure 285

$$\frac{d^2 \sigma_{CC}^{e^{\pm} p}}{dx dQ^2} = \frac{1 \pm P}{2} \frac{G_F^2}{2\pi x} \left[\frac{M_W^2}{M_W^2 + Q^2} \right] \cdot \sigma_{r,CC}^{e^{\pm} p}$$
 (5)

$$\sigma_{r,CC}^{e^{\pm}p} = Y_{+}\tilde{W}_{2}^{\pm} \mp Y_{-}x\tilde{W}_{3}^{\pm} - y^{2}\tilde{W}_{L}^{\pm}, \tag{6}$$

where P represents the lepton beam polarisation. At LO in α_s , the CC e^+p and e^-p cross sections are sensitive to dif-246 ferent combinations of the quark flavour densities.

$$\sigma_{rCC}^{e^+p} \approx x[\overline{u} + \overline{c}] + (1 - y)^2 x[d + s], \tag{7}$$

$$\sigma_{rCC}^{e^{-p}} \approx x[u+c] + (1-y)^2 x[\overline{d} + \overline{s}], \tag{8}$$

 $_{\it 247}~{\rm Here}~U~{\rm and}~D~{\rm denote}$ the sum over up- and down-type quarks; $^{\it 298}$ the latter include also strange and beauty quarks and the former charm quarks.

ferred to as coefficient functions.

few GeV^2 to about 10^5 GeV^2 , crossing heavy-quark mass $_{305}$ CT(CTEQ), NNPDF, and HERAPDF. HERAFitter implethresholds, thus the treatment of heavy quark (charm and 306 ments different variants of the GM-VFN scheme and they beauty) production and the chosen values of their masses becomes important. There are different approaches to the treatment of heavy quark production that would be equivalent if calculations could be carried out to all orders in α_s , but which differ at finite order. Several variants of these schemes 310 are implemented in HERAFitter and they are briefly dis-311 cussed below.

Zero-Mass Variable Flavour Number (ZM-VFN)[2]: In this 314 scheme, the heavy quarks appear as partons in the proton at 315 Q^2 values above $\sim m_h^2$ (heavy quark mass) and the heavy 316 quarks are then treated as massless in both the initial and 317 final states of the hard scattering process. The lowest order process is the scattering of the lepton off the heavy quark via (electroweak) boson exchange. This scheme is expected to be reliable in the region with $Q^2 \gg m_h^2$. In HERAFitter 321 this scheme is available for the DIS structure function cal- 322 culation via the interface to the QCDNUM [26] package, thus 323 it benefits from the fast QCDNUM convolution engine.

Fixed Flavour Number (FFN)[3-5]: In this scheme only the ³²⁶ gluon and the light quarks are considered as partons within 327 the proton and massive quarks are produced perturbatively 328 in the final state. The lowest order process is the heavy quark- 329 antiquark pair production via boson-gluon fusion. In HERA- 330 Fitter this scheme can be accessed via the QCDNUM imple- 331 mentation or through the interface to the open-source code 332

scheme is reliable for $Q^2 \sim m_h^2$. In QCDNUM, the calculation of The inclusive CC ep cross section, analogous to the NC 284 the heavy quark contributions to DIS structure functions are available at Next-to-Leading-Order (NLO) and only electromagnetic exchange contributions are taken into account. In 287 the OPENQCDRAD implementation the heavy quark contribu-(5) 288 tions to CC structure functions are also available and, for the NC case, the QCD corrections to the massive Wilson coef-(6) 290 ficients at Next-to-Next-to Leading Order (NNLO) and, for 291 the NC case, the QCD corrections to the coefficient func-292 tions at Next-to-Next-to Leading Order (NNLO) are pro-²⁹³ vided at the best currently known approximation [43]. The 294 OPENQCDRAD implementation also uses the running heavy-(7) 295 quark mass [44] in the $\overline{\rm MS}$ scheme. This scheme has the advantage of reducing the sensitivity of the DIS cross sections (8) 297 to higher order corrections, and improving the theoretical precision of the mass definition.

299 General-Mass Variable Flavour Number (GM-VFN)[6]: In Beyond LO, the QCD predictions for the DIS structure $_{\tiny 300}$ these schemes, heavy quark production is treated for Q^2 \sim functions are obtained by convoluting the PDFs with appro- $_{\scriptscriptstyle 301}$ m_h^2 in the FFN scheme and for $Q^2\gg m_h^2$ in the massless priate hard-process scattering matrix elements, which are re- 302 scheme with a suitable interpolation inbetween. The details 303 of this interpolation differ between different implementa-The DIS measurements span a large range of Q^2 from 304 tions. The PDF groups that use GM-VFN schemes are MSTW, are presented below:

- GM-VFN Thorne-Roberts scheme: The Thorne-Roberts (TR) scheme [45] was designed to provide a smooth transition from the massive FFN scheme at low scales $Q^2 \sim m_h^2$ to the massless ZM-VFNS scheme at high scales $Q^2 \gg m_h^2$. However, the original version was technically difficult to implement beyond NLO, and was updated to the TR' scheme [46]. There are two different variants of the TR' schemes: TR' standard (as used in MSTW PDF sets [16, 46]) and TR' optimal [47], with a smoother transition across the heavy quark threshold region. Both variants are accessible within the HERAFitter package at LO, NLO and NNLO.
- GM-VFN ACOT scheme: The Aivazis-Collins-Olness-Tung (ACOT) scheme belongs to the group of VFN factorisation schemes that use the renormalisation method of Collins-Wilczek-Zee (CWZ) [48]. This scheme unifies the low scale $Q^2 \sim m_h^2$ and high scale $Q^2 > m_h^2$ regions with a smooth interpolation across the full energy range. Within the ACOT package, different variants of the ACOT scheme are available: ACOT-Full [49], S-ACOT- χ [50, 51], ACOT-ZM [49], $\overline{\text{MS}}$ at LO and NLO. For the longitudinal structure function higher order calculations are also available. A comparison of PDFs extracted from the QCD fits to the HERA data with the TR' and ACOT-Full schemes is illustrated in Fig. 3 (taken from [40]).

324

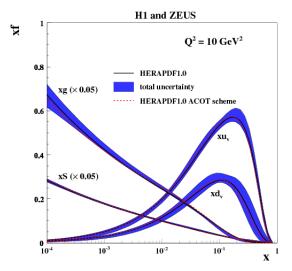

Fig. 3 Overview showing the u- and d-valence, the total sea (scaled), and gluon (scaled) PDFs of the NLO HERAPDF1.0 set [40] with their total uncertainty at the scale of $Q^2 = 10 \text{ GeV}^2$ obtained using the TR' scheme and compared to the PDFs obtained with the ACOT scheme 361 using the k-factor technique (red).

3.2 Electroweak Corrections to DIS

Calculations of higher-order electroweak corrections to DIS scattering at HERA are available in HERAFitter in the onshell scheme. In this scheme the gauge bosons masses M_W and M_Z are treated as basic parameters together with the top, Higgs and fermion masses. These electroweak corrections are based on the EPRC package [52]. The code calculates the running of the electromagnetic coupling α using the most recent parametrisation of the hadronic contribution [53], as well as an older version from Burkhard [54].

3.3 Diffractive PDFs

Diffractive parton distributions (DPDFs) can be determined from QCD fits to diffractive cross sections in a similar way to the determination of the standard PDFs. About 10% of deep inelastic interactions at HERA are diffractive, such that the interacting proton stays intact $(ep \rightarrow eXp)$. The proton is well separated from the rest of the hadronic final state by a large rapidity gap. This is interpreted as the dissociation of the virtual photon into hadronic system X with an invariant mass much smaller than the photon-proton c.o.m. energy $W = ys - Q^2 + m_p^2(1 - y)$, where m_p is proton's mass. Such a process is assumed to be mediated by the exchange of a hard Pomeron or a secondary Reggeon with vacuum quantum numbers. This factorisable pomeron picture has proved remarkably successful in the description of most of 382 where S is the squared c.o.m. beam energy, the parton mothe diffractive data.

In addition to the usual DIS variables x, Q^2 , extra kinematic variables are needed to describe the diffractive process. These are the squared four-momentum transfer of the exchange Pomeron or Reggeon, t, and the mass M_X of the diffractively produced final state. In practice, the variable M_X is often replaced by dimensionless quantity $\beta = \frac{Q^2}{M_X^2 + Q^2 - t}$ In models based on a factorisable pomeron, β may be viewed at LO as the fraction of the pomeron longitudinal momentum which is carried by the struck parton, $x = \beta x_{IP}$.

For the inclusive case, the diffractive cross-section reads as:

$$\frac{d\sigma}{d\beta dQ^2 dx_{IP} dt} = \frac{2\pi\alpha^2}{\beta Q^4} \left(1 + (1-y)^2\right) \overline{\sigma}^{D(4)}(\beta, Q^2, x_{IP}, t)$$
(9)

with the "reduced cross-section":

$$\overline{\mathbf{\sigma}}^{D(4)} = F_2^{D(4)} - \frac{y^2}{1 + (1 - y)^2} F_L^{D(4)}. \tag{10}$$

Substituting $x = x_{IP}\beta$ we can relate Eq. 9 to the standard 360 DIS formula. In this way, the diffractive structure functions can be expressed as convolutions of calculable coefficient functions with the diffractive quark and gluon distribution functions, which in general depend on x_{IP} , Q^2 , β , t.

The diffractive PDFs in HERAFitter [55, 56] are implemented as a sum of two factorised contributions:

$$\Phi_{IP}(x_{IP},t) f_a^{Pom}(\beta,Q^2) + \Phi_{IR}(x_{IP},t) f_a^{IR}(\beta,Q^2),$$
 (11)

where $\Phi(x_{I\!\!P},t)$ are the Reggeon and Pomeron fluxes. The Reggeon PDFs, f_a^{IR} are fixed as those of the pion, while the Pomeron PDFs, f_a^{IR} , can be obtained from a fit to the data.

3.4 Drell-Yan Processes in pp or $p\bar{p}$ Collisions

Drell-Yan process provides further valuable information about PDFs. In pp and $p\bar{p}$ scattering, the Z/γ^* and W production probe bi-linear combinations of quarks. Complementary in-371 formation on the different quark densities can be obtained from the W asymmetry (d, u) and their ratio, the ratio of the W and Z cross sections (sensitive to the flavour composition of the quark sea, in particular to the s-quark density), and associated W and Z production with heavy quarks (sensitive to s- and c-quark densities). Measurements at large boson $p_T \gtrsim M_{W,Z}$ are potentially sensitive to the gluon density [57].

At LO the DY NC triple differential cross section in invariant mass M, boson rapidity y and lepton scattering angle $\cos \theta$ in the parton c.o.m. frame can be written as [58, 59]:

$$\frac{d^{3}\sigma}{dMdyd\cos\theta} = \frac{\pi\alpha^{2}}{3MS} \sum_{q} \hat{\sigma}^{q}(\cos\theta, M) \times \left[f_{q}(x_{1}, Q^{2}) f_{\bar{q}}(x_{2}, Q^{2}) + (q \leftrightarrow \bar{q}) \right], \quad (12)$$

mentum fractions are given by $x_{1,2} = \frac{M}{\sqrt{S}} \exp(\pm y), f_q(x_1, Q^2)$

cross section.

The corresponding CC triple differential cross section has

$$\frac{d^{3}\sigma}{dMdyd\cos\theta} = \frac{\pi\alpha^{2}}{48S\sin^{4}\theta_{W}} \frac{M^{3}(1-\cos\theta)^{2}}{(M^{2}-M_{W}^{2}) + \Gamma_{W}^{2}M_{W}^{2}} \times \sum_{q_{1},q_{2}} V_{q_{1}q_{2}}^{2} f_{q_{1}}(x_{1},Q^{2}) f_{q_{2}}(x_{2},Q^{2}),$$
(13)

where $V_{q_1q_2}$ is the Cabibbo-Kobayashi-Maskawa (CKM) quark mixing matrix and M_W and Γ_W are the W boson mass and decay width, respectively.

391

The simple form of these expressions allows analytic calculation of integrated cross sections. In both NC and CC expressions the PDFs depend only on boson rapidity y and invariant mass M, while the integral in $\cos \theta$ can be solved analytically even for the case of realistic kinematic cuts.

and MC techniques are often employed. Currently, the predictions for W and Z/γ^* production are available up to NNLO₄₄₅ more involved with order due to an increasing number of and the predictions for W, Z in association with heavy flavour $\frac{1}{446}$ Feynman diagrams. Nowadays even the most advanced perquarks is available to NLO. There are several possibilities for obtaining the theoretical predictions for DY production in HERAFitter.

The NLO and NNLO calculations are computing power and time consuming and k-factor or fast grid techniques must be employed (see section 4 for details), interfaced to programs such as MCFM [60–62], available for NLO calculations, or FEWZ [63] and DYNNLO [64] for NLO and NNLO.

3.5 Jet Production in ep and pp or $p\bar{p}$ Collisions

The cross section for production of high-transverse-momentum hadronic jets is sensitive to the high-x gluon PDF (see e.g. Ref. [16]) therefore this process can be used to improve the determination of the gluon PDF, which is particularly important for Higgs production and searches for new physics. Jet production cross sections are currently known only to NLO, although calculations for higher-order contributions to jet production in proton-proton collisions are now quite advanced [65-67]. Within HERAFitter, the NLOJet++ program [68, 69] may be used for calculations of jet production. Similarly to the DY case, the calculation is very demanding in terms of computing power. Therefore fast grid techniques are used to facilitate the QCD analyses including jet cross section measurements. in ep, pp and $p\bar{p}$ collisions (for details see section 4).

3.6 Top-quark Production in pp or $p\bar{p}$ Collisions

At the LHC top-quark pairs $(t\bar{t})$ are produced at hadron col-474 calculation at each step, but still requires a couple of repetiliders dominantly via gg fusion. Thus LHC Measurements 475 tions depending on the analysis.

are the PDFs, and $\hat{\sigma}^q$ is the parton-parton hard scattering 428 of the $t\bar{t}$ cross sections can provide additional constraints on the gluon density at medium to high values of x, on α_s and on the top-quark mass, m_t [70]. Precise predictions for the total $t\bar{t}$ cross section are available to full NNLO [71]. They can be computed within HERAFitter via an interface to the program HATHOR [72]. Differential $t\bar{t}$ cross section predictions can be obtained using MCFM [62, 73–76] interfaced to HERAFitter with fast grid techniques.

> Single top quarks are produced via electroweak interactions and single-top cross sections can be used, for example, to probe the ratio of the u and d densities in the proton as well as the b-quark PDF. Predictions for single-top produc-440 tion are available to NLO accuracy using MCFM.

441 4 Computational Techniques

Precise measurements require theoretical predictions with Beyond LO, the calculations can no longer be done quickly equally good accuracy in order to maximise their impact in 444 PDF fits. Perturbative calculations, however, get more and turbative techniques in combination with modern computing hardware do not lead to sufficiently small turn-around times. The direct inclusion of computationally demanding higherorder calculations into iterative fits therefore is not possible. Relying on the fact that a full repetition of the perturbative 452 calculation for arbitrary changes in input parameters is not ⁴⁵³ necessary at each iteration step, two methods have been developed to resolve this problem: the techniques of k-factors and fast grids. Both are available in HERAFitter and de-456 scribed as follows.

4.1 k-factor Technique

The k-factors are defined as the ratio of the prediction of a 459 higher-order (slow) pQCD calculation to a lower-order (fast) calculation. Because the k-factors depend on the phase space probed by the measurement, they have to be stored in a table including dependence on the relevant kinematic variables. Before the start of a fitting procedure, the table of k-factors has to be computed once for a given PDF with the time consuming higher-order code. In subsequent iteration steps the theory prediction is derived from the fast lower-order calculation multiplied by the pre-tabulated *k*-factors.

This procedure, however, neglects the fact that the kfactors can be PDF dependent, as a consequence, they have 470 to be re-evaluated for the newly determined PDF at the end 471 of the fit for the consistency check. Usually, the fit is repeated until input and output k-factors have converged. In summary, this technique avoids iteration of the higher-order

An implementation of k-factor technique in HERAFitter 527 an interface between the higher-order theory programs and is used for the fast approximation of the time-consuming 528 the fast interpolation frameworks. Work in that direction is GM-VFN schemes for heavy quarks in DIS. "FAST" heavy- 529 ongoing for both packages and described in more details in flavour schemes are implemented with k-factors defined as 530 the following: the ratio of calculations at the same perturbative order but for massive vs. massless quarks, e.g. NLO (massive)/NLO (massless). These *k*-factors are calculated only for the starting PDF and hence, the "FAST" heavy flavour schemes should 33 only be used for quick checks, i.e. full heavy flavour schemes 534 are normally recommended. For the ACOT case, due to long computation time, the k-factors are used in the default settings in HERAFitter. 538

4.2 Fast Grid Techniques

Fast grid techniques exploit the fact that iterative PDF fitting procedures do not impose completely arbitrary changes to the types and shapes of the parameterised functions that represent each PDF. Instead, it can be assumed that a generic 545 PDF can be approximated by a set of interpolating functions 546 with a sufficient number of support points. The accuracy of 547 this approximation can be checked and optimised in various ways with the simplest one being an increase in the number 549 of support points. Having ensured that the approximation 550 bias is negligibly small compared to the experimental and theoretical accuracy for all practical purposes, this method can be used to perform the time consuming higher-order calculations (Eq. 1) only once for the set of interpolating 554 functions. Further iteration of a cross section evaluation for 555 a particular PDF set is fast and implies only sums over the 556 set of interpolators multiplied by factors depending on the 557 PDF. The approach applies equally for the cross sections of 558 processes involving one or two hadrons in the initial state as 559 well as to their renormalisation and factorisation scale variation.

This technique was pioneered in the fastNLO project $[77]_{562}$ to facilitate the inclusion of notoriously time consuming jet 563 cross sections at NLO into PDF fits. The APPLGRID [78] 564 project developed an alternative method and, in addition to 565 jets, extended its applicability to other scattering processes, 556 such as DY, heavy quark pair production is association with 557 boson production, etc. While differing in their interpolation 568 and optimisation strategies, both packages construct tables 569 with grids for each bin of an observable in two steps: in the 570 first step, the accessible phase space in the parton momentum fractions x and the renormalisation and factorisation scales μ_R and μ_F is explored in order to optimise the table 571 **5 Fit Methodology** size. The second step consists of the actual grid filling for the requested observables. Higher-order cross sections can 572 When performing a QCD analysis to determine PDFs there then be restored very efficiently from the pre-produced grids 573 are various assumptions and choices to be made concerning, while varying externally provided PDF sets, μ_R and μ_F , or 574 for example, the functional form of the input parametrisathe strong coupling $\alpha_s(\mu_R)$. The approach can in principle 575 tion, the treatment of heavy quarks and their mass values, albe extended to arbitrary processes, but requires to establish 576 ternative theoretical calculations, alternative representations

- The fastNLO project [77] has been interfaced to the NLOJet++ program [68] for the calculation of jet production in DIS [79] as well as 2- and 3-jet production in hadron-hadron collisions at NLO [69, 80]. To demonstrate the applicability to higher-orders, threshold corrections at 2-loop order, which approximate the NNLO for the inclusive jet cross section, have been included into the framework [81] following Ref. [82].
- The latest version of fastNLO convolution program [83] allows for a creation of tables where renormalisation and factorisation scales can be varied as a function of two pre-defined observables, e.g. jet transverse momentum p_{\perp} and Q for DIS. The fastNLO code is available online [84] where also the jet cross-section grids computed for kinematics of various experiments can be downloaded. Dedicated fastNLO libraries and tables with theory predictions for comparison to particular cross section measurements are included into the HERAFitter package. For the HERAFitter implementation, the evaluation of the strong coupling constant is taken consistently with the PDF evolution from the QCDNUM code.
- In the APPLGRID package [78, 85], in addition to the jet cross sections from NLOJet++ in $pp(\bar{p})$ and DIS processes, the calculations of DY production are also implemented. The look-up tables (grids) can be generated with the customised versions of the MCFM parton level DY generator [60-62]. The variation of the renormalisation and factorisation scales is possible a posteriori, when calculating theory predictions with the APPLGRID tables, and independent variation of the strong coupling constant is also allowed. For NNLO predictions in HERAFitter, the k-factors technique can be also applied within the APPLGRID framework.

The HERAFitter interface to APPLGRID was in particular used by the ATLAS collaboration to extract the strange quark density of the proton from W and Z cross sections [86]. An illustration of ATLAS PDFs extracted employing these techniques is displayed in Fig. 4 together with the comparison to global PDF sets CT10 [17] and NNPDF2.1 [18] (taken from [86]).

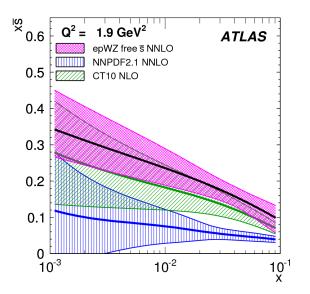

Fig. 4 The strange antiquark density versus x for the ATLAS epWZ free sbar NNLO fit [86] (magenta band) compared to predictions 610 integration of Eq. 15 is required in order to satisfy the QCD from NNPDF2.1 (blue hatched) and CT10 (green hatched) at Q^2 = 1.9 GeV². The ATLAS fit was performed using a k-factor approach for NNLO corrections.

tests. The methodology employed by HERAFitter relies on $_{\scriptsize 618}$ form reads a flexible and modular framework that allows for independent integration of the state-of-the-art techniques, either related to the inclusion of a new theoretical calculation, or of new approaches to treat data and their uncertainties.

In this section we describe the available options for the fit methodology in HERAFitter. In addition, as an alternative approach to a complete QCD fit, the Bayesian reweighting method, which is also available in HERAFitter, is described.

5.1 Functional Forms for PDF Parametrisation

The PDFs can be parametrised using several predefined functional forms and different flavour decompositions:

Standard Polynomials: The standard polynomial form is the most commonly used. A polynomial functional form is used to parametrise the x-dependence of the PDFs, where index j cesses available in HERAFitter. This is possible via an indenotes each parametrised PDF flavour:

$$xf_j(x) = A_j x^{B_j} (1 - x)^{C_j} P_j(x).$$
 (14)

 xd_v , the gluon distribution xg, and the u-type and d-type sea, 636 accessed from LHAPDF as produced with the drawing tools $x\bar{U}, x\bar{D}$, where $x\bar{U} = x\bar{u}, x\bar{D} = x\bar{d} + x\bar{s}$ at the starting scale, 637 available in HERAFitter.

which is chosen below the charm mass threshold. The form of polynomials $P_i(x)$ can be varied. The form $(1 + \varepsilon_i \sqrt{x} +$ $D_i x + E_i x^2$ is used for the HERAPDF [40] with additional constraints relating to the flavour decomposition of the light sea. This parametrization is termed HERAPDF-style. The polynomial can also be parametrized in the CTEQ-style, $P_i(x)$ takes the form $e^{a_3x}(1+e^{a_4}x+e^{a_5}x^2)$ and, in contrast to the HERAPDF-style, this is positive by construction. QCD number and momentum sum rules are used to determine the normalisations A for the valence and gluon distributions, and the sum-rule integrals are solved analytically.

Bi-Log-Normal Distributions: This parametrisation is motivated by multi-particle statistics and has the following functional form:

$$xf_j(x) = a_j x^{p_j - b_j \log(x)} (1 - x)^{q_j - d_j \log(1 - x)}.$$
 (15)

This function can be regarded as a generalisation of the standard polynomial form described above, however, numerical sum rules.

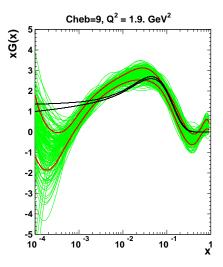

612 Chebyshev Polynomials: A flexible parametrisation based on the Chebyshev polynomials can be employed for the gluon of the fit χ^2 , different ways of treating correlated system- 614 and sea distributions. Polynomials with argument $\log(x)$ are atic uncertainties. It is useful to be able to discriminate or 615 considered or better modelling the low-x asymptotic of those quantify the effect of the chosen ansatz, within a common 616 PDFs. The polynomials are multiplied by a factor of (1-x)framework, and HERAFitter is optimally designed for such $_{617}$ to ensure that they vanish as $x \to 1$. The resulting parametric

$$xg(x) = A_g(1-x) \sum_{i=0}^{N_g-1} A_{g_i} T_i \left(-\frac{2\log x - \log x_{\min}}{\log x_{\min}} \right),$$
 (16)

$$xS(x) = (1 - x) \sum_{i=0}^{N_S - 1} A_{S_i} T_i \left(-\frac{2 \log x - \log x_{\min}}{\log x_{\min}} \right), \qquad (17)$$

where T_i are first-type Chebyshev polynomials of order i. The normalisation factor A_g is derived from the momentum sum rule analytically. Values of $N_{g,S}$ to 15 are allowed, however the fit quality is already similar to that of the standardpolynomial parametrisation from $N_{g,S} \ge 5$ and has a similar number of free parameters. Fig. 5 (taken from [87]) shows a 625 comparison of the gluon density obtained with the parametrisation Eqs. 16, 17 to the standard-polynomial one, for $N_{g,S}$ =

628 External PDFs: HERAFitter also provides the possibility 629 to access external PDF sets, which can be used to compute 630 theoretical predictions for the cross sections for all the pro-632 terface to LHAPDF [37, 38] providing access to the global (14) 633 PDF sets. HERAFitter also allows to evolve PDFs from 634 LHAPDF with QCDNUM using the corresponding grids as a The parametrised PDFs are the valence distributions xu_v and $_{635}$ starting scale. Fig. 6 illustrates a comparison of various PDFs

Fig. 5 The gluon density is shown at the starting scale. The black lines correspond to the uncertainty band of the gluon distribution using a standard parametrisation and it is compared to the case of the Chebyshev parametrisation [87]. The uncertainty band for the latter case is estimated using the Monte Carlo technique ?? with the green lines denoting fits to data replica. Red lines indicate the standard deviation about the mean value of these replicas.

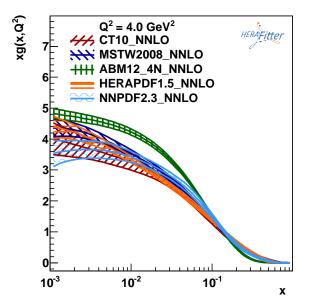

Fig. 6 The gluon PDF as extracted by various PDF groups at the scale of $Q^2 = 4 \text{ GeV}^2$, plotted using the drawing tools from HERAFitter.

5.2 Representation of χ^2

The PDF parameters are determined in HERAFitter by minimisation of the χ^2 function taking into account correlated 680 Any source of measured systematic uncertainty can be treated and uncorrelated measurement uncertainties. There are vari- 681 as additive or multiplicative. The statistical uncertainties can ous forms of the χ^2 e.g. using a covariance matrix or pro- 682 be included as additive or Poisson. Minimisation with reviding nuisance parameters to encode the dependence of 683 spect to nuisance parameters is performed analytically, howeach correlated systematic uncertainty for each measured 684 ever for more detailed studies of correlations individual nuidata point. The options available in HERAFitter are fol- 605 sance parameters can be included in the MINUIT minimisalowing.

Covariance Matrix Representation: For a data point μ_i with a corresponding theory prediction m_i , the χ^2 function can be expressed in the following form:

$$\chi^{2}(m) = \sum_{i,k} (m_{i} - \mu_{i}) C_{ik}^{-1}(m_{k} - \mu_{k}), \tag{18}$$

where the experimental uncertainties are given as a covariance matrix $C_{i,k}$ for measurements in bins i and k. The covariance matrix C_{ik} is given by a sum of statistical, uncorrelated and correlated systematic contributions:

$$C_{ik} = C_{ik}^{stat} + C_{ik}^{uncor} + C_{ik}^{sys}. (19)$$

Using this representation one cannot distinguish the separate effect of each source of systematic uncertainty. Nuisance Parameters Representation: In this case the χ^2 form is expressed as

$$\chi^{2}(m,b) = \sum_{i} \frac{\left[\mu_{i} - m_{i}\left(1 - \sum_{j} \gamma_{j}^{i} b_{j}\right)\right]^{2}}{\delta_{i,\text{unc}}^{2} m_{i}^{2} + \delta_{i,\text{stat}}^{2} \mu_{i} m_{i}\left(1 - \sum_{j} \gamma_{j}^{i} b_{j}\right)} + \sum_{j} b_{j}^{2},$$
(20)

where, $\delta_{i,\text{stat}}$ and $\delta_{i,\text{unc}}$ are relative statistical and uncorrelated systematic uncertainties of the measurement i. Further, γ_i^i quantifies the sensitivity of the measurement to the correlated systematic source j. The function χ^2 depends in addition on the set of systematic nuisance parameters b_i . This definition of the χ^2 function assumes that systematic uncertainties are proportional to the central prediction values (multiplicative errors), whereas the statistical uncertainties scale with the square root of the expected number of events.

During the χ^2 minimisation, the nuisance parameters b_i and the PDFs are determined, such that the effect of different sources of systematic uncertainties can be distinguished.

Mixed Form Representation: In some cases, the statistical and systematic uncertainties of experimental data are provided in different forms. For example, the correlated experimental systematic uncertainties are available as nuisance parameters but the bin-to-bin statistical correlations are given in the form of covariance matrix. HERAFitter offers the possibility to include such mixed forms of information. form of treating statistical, uncorrelated and correlated systematic uncertainties.

Three distinct methods for propagating experimental uncertainties to PDFs are implemented in HERAFitter and reviewed here: the Hessian, Offset, and Monte Carlo method.

Hessian (Eigenvector) method: The PDF uncertainties reflecting the uncertainties in experimental data are estimated by examining the shape of χ^2 in the neighbourhood of the minimum [88]. Following approach of Ref. [88], the Hessian matrix is defined by the second derivatives of χ^2 on the fitted PDF parameters. The matrix is diagonalised and the Hessian eigenvectors are computed. Due to orthogonality, these vectors correspond to independent sources of uncertainty in the obtained PDFs.

Offset method: The Offset method [89] uses the χ^2 function for the central fit, however only uncorrelated uncertainties are taken into account. The goodness of the fit can no longer be judged from the χ^2 since correlated uncertainties are ignored. The correlated uncertainties are propagated into the PDF uncertainties by performing variants of the fit with the experimental data varied by $\pm 1\sigma$ from the central value for each systematic source. The resulting deviations of the PDF parameters from the ones obtained in the central fit are statistically indepen- 740 dent, and they can be combined in quadrature to arrive 741 at the total PDF systematic uncertainty.

The uncertainties estimated by the offset method are generally larger than those from the Hessian method.

Monte Carlo method: The Monte-Carlo technique [90, 91] can also be used to determine PDF uncertainties. The uncertainties are estimated using pseudo-data replicas (typically > 100) randomly generated from the measurement central values and their systematic and statistical uncertainties taking into account all point-to-point correlations. The QCD fit is performed for each replica and the PDF central values and their experimental uncertainties are estimated from the distribution of the PDF parameters obtained in these fits, by taking the mean values and standard deviations over the replicas.

The MC method has been checked against the standard error estimation of the PDF uncertainties obtained by the Hessian method. A good agreement was found between the methods provided that Gaussian distributions of statistical and systematic uncertainties are assumed in the MC approach [36]. A comparison is illustrated global analysis [92].

MC to eigenvector representation as shown by [93]. Tools $749 \ m_c$, mass of the bottom quarks, m_b , and the value of $\alpha_s(M_Z)$.

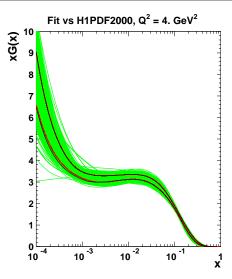

Fig. 7 Comparison between the standard error calculations as employed by the Hessian approach (black lines) and the MC approach (with more than 100 replicas) assuming Gaussian distribution for uncertainty distributions, shown here for each replica (green lines) together with the evaluated standard deviation (red lines) [36]. The black lines in the figure are difficult to see because agreement of the methods is so good that thet are mostly covered by the red lines.

to perform this transformation are provided with HERAFitter and were recently employed for the representation of correlated sets of PDFs at different perturbative order [94].

The nuisance parameter representation of χ^2 in Eq. 20 is derived assuming symmetric experimental errors, however, the published systematic uncertainties are often asymmetric. HERAFitter provides the possibility to use asymmetric systematic uncertainties. The implementation relies on the assumption that asymmetric uncertainties can be described by a parabolic function. The nuisance parameter in Eq. 20 is modified as follows

$$\gamma_j^i \to \omega_j^i b_j + \gamma_j^i,$$
 (21)

where the coefficients ω_i^i , γ_i^i are defined from the maximum and minimum shifts of the cross sections due to variaion of the systematic uncertainty j, S_{ij}^{\pm} ,

$$\omega_{j}^{i} = \frac{1}{2} \left(S_{ij}^{+} + S_{ij}^{-} \right), \qquad \gamma_{j}^{i} = \frac{1}{2} \left(S_{ij}^{+} - S_{ij}^{-} \right). \tag{22}$$

5.4 Treatment of the Theoretical Input Parameters

in Fig. 7. Similar findings were reported by the MSTW 744 The results of a QCD fit depend not only on the input data but also on the input parameters used in the theoretical cal-Since the MC method requires large number of replicas, 746 culations. Nowadays, PDF groups address the impact of the the eigenvector representation is a more convenient way 747 choices of theoretical parameters by providing alternative to store the PDF uncertainties. It is possible to transform 748 PDFs with different choices of the mass of the charm quarks,

Other important aspects are the choice of the functional form for the PDFs at the starting scale and the value of the starting scale itself. HERAFitter provides the possibility of different user choices of all these inputs to the theory.

5.5 Bayesian Reweighting Techniques

As an alternative to performing a full QCD fit, HERAFitter allows the user to assess the impact of including new data in an existing fit using the Bayesian Reweighting technique. The method provides a fast estimate of the impact of new data on PDFs. Bayesian Reweighting was first proposed for PDF sets delivered in the form of MC replicas by [90] and further developed by the NNPDF Collaboration [95, 96]. More recently, a method to perform Bayesian Reweighting studies starting from PDF fits for which uncertainties are provided in the eigenvectors representation has been also developed [92]. The latter is based on generating replica sets by introducing Gaussian fluctuations on the central PDF set with a variance determined by the PDF uncertainty given by the eigenvectors. Both reweighting methods are imple-781 6 Alternatives to DGLAP Formalism mented in HERAFitter.

average of the predictions obtained from the ensemble as

$$\langle \mathcal{O}(\{f\}) \rangle = \frac{1}{N_{\text{rep}}} \sum_{k=1}^{N_{\text{rep}}} \mathcal{O}(f^k),$$
 (23)

and the uncertainty as the standard deviation of the sample.

Upon inclusion of new data the prior probability distribution, given by the prior PDF set, is updated according to Bayes Theorem and the weight of each replica, w_k , is updated according to

$$w_k = \frac{(\chi_k^2)^{\frac{1}{2}(N_{\text{data}} - 1)} e^{-\frac{1}{2}\chi_k^2}}{\frac{1}{N_{\text{ren}}} \sum_{k=1}^{N_{\text{rep}}} (\chi_k^2)^{\frac{1}{2}(N_{\text{data}} - 1)} e^{-\frac{1}{2}\chi_k^2}},$$
(24)

specific replica for which the weight is calculated and χ_k^2 is 801 are embedded in the dipole scattering amplitude. the chi-square of the new data obtained using the k-th PDF 802 data can be computed as the weighted average,

$$\langle \mathcal{O}(\{f\}) \rangle = \frac{1}{N_{\text{rep}}} \sum_{k=1}^{N_{\text{rep}}} w_k \mathcal{O}(f^k).$$
 (25)

To simplify the use of reweighted set, an unweighted set (i.e. a set of equiprobable replicas which incorporates the information contained in the weights) is generated according to the unweighting procedure described in [95]. The number of effective replicas of a reweighted set is measured by its Shannon Entropy [96]

$$N_{\rm eff} \equiv \exp\left\{\frac{1}{N_{\rm rep}} \sum_{k=1}^{N_{\rm rep}} w_k \ln(N_{\rm rep}/w_k)\right\},\tag{26}$$

which corresponds to the size of a refitted equiprobable replica set containing the same amount of information. This number of effective replicas, $N_{\rm eff}$, gives an indicative measure of the 774 optimal size of an unweighted replica set produced using 775 the reweighting/unweighting procedure. No extra informa-776 tion is gained by producing a final unweighted set that has a number of replicas (significantly) larger than $N_{\rm eff}$. Clearly $_{778}$ if $N_{\rm eff}$ is much smaller than the original number of replicas the new data have great impact, but it is unreliable to use the new reweghted set. Instead a full refit should be performed.

The Bayesian Reweighting technique relies on the fact 782 The QCD calculations based on the DGLAP [21-25] evothat MC replicas of a PDF set give a representation of the 783 lution equations are very successful in describing all releprobability distribution in the space of PDFs. In particular, 784 vant hard scattering data in the perturbative region $Q^2 \gtrsim$ the PDFs are represented as ensembles of N_{rep} equiprobable 785 $1 \,\text{GeV}^2$. At small-x and small- Q^2 the DGLAP dynamics may (i.e. having all weight equal to unity) replicas, $\{f\}$. The central value for a given observable, $\mathcal{O}(\{f\})$, is computed as the TBT based dipole models and other higher twist effects. Differ-788 ent approaches that are alternatives to the DGLAP formal-189 ism can be used to analyse DIS data in HERAFitter. These 790 include several different dipole models and the use of trans-(23) verse momentum dependent, or unintegrated PDFs (uPDFs).

792 6.1 Dipole Models

The dipole picture provides an alternative approach to the 794 proton-virtual photon scattering at low x providing the description of both inclusive and diffractive processes. In this approach, the virtual photon fluctuates into a $q\bar{q}$ (or $q\bar{q}g$) (24) 797 dipole which interacts with the proton [97]. The dipoles can 798 be considered as quasi-stable quantum mechanical states, which have very long life time $\propto 1/m_p x$ and a size which is where N_{data} is the number of new data points, k denotes the 800 not changed by scattering. The dynamics of the interaction

Several dipole models which assume different behaviour replica. Given a PDF set and a corresponding set of weights, 803 of the dipole-proton cross sections are implemented in HERAFitter: which describes the impact of the inclusion of new data, the 804 the Golec-Biernat-Wüsthoff (GBW) dipole saturation model [32], prediction for a given observable after inclusion of the new 805 the colour glass condensate approach to the high parton density regime called the Iancu-Itakura-Munier (IIM) dipole model [33] and a modified GBW model which takes into account the ef-(25) 808 fects of DGLAP evolution called the Bartels-Golec-Kowalski 809 (BGK) dipole model [34].

section $\sigma_{\rm dip}$ is given by

$$\sigma_{\text{dip}}(x, r^2) = \sigma_0 \left(1 - \exp\left[-\frac{r^2}{4R_0^2(x)} \right] \right),$$
 (27)

the quark and the antiquark, and R_0^2 is an x-dependent scale 852 ton splitting [21, 24, 25] according to the CCFM evolution parameter which represents the spacing of the gluons in the 853 equation [29, 118, 119]. proton. $R_0^2(x) = (x/x_0)^{\lambda} 1 / \text{GeV}^2$ is called the saturation radius. The cross-section normalisation σ_0 , x_0 , and λ are pa- 855 logarithmically enhanced small-x contributions to all orders rameters of the model commonly fitted to the DIS data. This 856 in perturbation theory, both in the hard scattering coeffimodel gives exact Bjorken scaling when the dipole size r is 857 cients and in the parton evolution, fully taking into account

IIM model: The IIM model assumes an improved expres- 860 sion for the dipole cross section which is based on the Balitsky scheme, where only the boson-gluon fusion process ($\gamma^* g^* \to \gamma^* g^*$) Kovchegov equation [98]. The explicit formula for σ_{dip} can $q\bar{q}$ is included. The masses of the quarks are explicitly inbe found in [33]. The alternative scale parameter \tilde{R} , x_0 and 863 cluded as parameters of the model. In addition to $\gamma^*g^* \to q\bar{q}$, λ are fitted parameters of the model.

BGK model: The BGK model is a modification of the GBW model assuming that the spacing R_0 is inverse of the gluon 866 CCFM Grid Techniques: The CCFM evolution cannot be density and taking into account the DGLAP evolution of the 867 written easily in an analytic closed form. For this reason a latter. The gluon density parametrised at some starting scale 868 Monte Carlo method is employed, which is however timeby Eq. 14 is evolved to larger scales using DGLAP evolu- 8699 consuming, and cannot be used in a straightforward manner tion.

BGK model with valence quarks: The dipole models are 872 124], the kernel $\tilde{\mathscr{A}}(x'', k_t, p)$ is determined from the Monte valid in the low-x region only, where the valence quark con- 873 Carlo solution of the CCFM evolution equation, and then tribution to the total proton momentum is 5% to 15% for $_{874}$ folded with the non-perturbative starting distribution $\mathcal{A}_0(x)$ x from 0.0001 to 0.01 [99]. The new HERA F_2 measurements have a precision which is better than 2%. Therefore, in HERAFitter the contribution of the valence quarks can be taken into account in the original BGK model [100].

6.2 Transverse Momentum Dependent PDFs

828

QCD calculations of multiple-scale processes and complex final-states require in general transverse-momentum dependent (TMD) [13], or unintegrated, parton distribution and parton decay functions [101–109]. The TMD factorisation has been proven recently [13] for inclusive DIS. For particular hadron-hadron scattering processes, like heavy flavor, vector boson and Higgs production, TMD factorisation has also been proven in the high-energy (small-x) limit [110– 112].

In the framework of high-energy factorisation [110, 113, 114] the DIS cross section can be written as a convolution in both longitudinal and transverse momenta of the TMD parton density function $\mathcal{A}(x, k_t, \mu)$ with the off-shell partonic matrix elements, as follows

$$\sigma_j(x,Q^2) = \int_x^1 dz \int d^2k_t \ \hat{\sigma}_j(x,Q^2,z,k_t) \ \mathscr{A}\left(z,k_t,\mu_F^2\right) \tag{28}$$

GBW model: In the GBW model the dipole-proton cross 846 with the DIS cross sections σ_i , (j=2,L) related to the structure functions F_2 and F_L . The hard-scattering kernels $\hat{\sigma}_i$ of Eq. 28, are k_t -dependent and the evolution of the transverse-(27) 849 momentum dependent gluon density $\mathscr A$ is obtained by combining the resummation of small-*x* logarithmic contributions where r corresponds to the transverse separation between 851 [115–117] with medium-x and large-x contributions to par-

> The factorisation formula (28) allows resummation of the dependence on the factorisation scale μ_F and on the factorisation scheme [120, 121].

> The cross section σ_i , (j = 2, L) is calculated in a FFN the contribution from valence quarks is included via $\gamma^* q \rightarrow q$ by using a CCFM evolution of valence quarks [122, 123].

> 870 in a fit program.

Following the convolution method introduced in [123,

$$x\mathscr{A}(x,k_t,p) = x \int dx' \int dx'' \mathscr{A}_0(x') \widetilde{\mathscr{A}}(x'',k_t,p) \,\delta(x'x''-x)$$
$$= \int dx' \mathscr{A}_0(x') \cdot \frac{x}{x'} \,\widetilde{\mathscr{A}}\left(\frac{x}{x'},k_t,p\right), \tag{29}$$

where k_t denotes the transverse momentum of the propagator gluon and p is the evolution variable.

The kernel $\tilde{\mathcal{A}}$ incorporates all of the dynamics of the $_{878}$ evolution. It is defined on a grid of $50\otimes50\otimes50$ bins in x, k_t, p . The binning in the grid is logarithmic, except for the longitudinal variable x where 40 bins in logarithmic spacing below 0.1, and 10 bins in linear spacing above 0.1 are used.

Calculation of the cross section according to Eq. 28 involves a multidimensional Monte Carlo integration which is time consuming and suffers from numerical fluctuations. This cannot be employed directly in a fit procedure involving the calculation of numerical derivatives in the search for the minimum. Instead the following equation is applied:

$$\sigma(x, Q^2) = \int_x^1 dx_g \mathscr{A}(x_g, k_t, p) \hat{\sigma}(x, x_g, Q^2),$$

$$= \int_x^1 dx' \mathscr{A}_0(x') \cdot \tilde{\sigma}(x/x', Q^2),$$
 (30)

 $\sigma_j(x,Q^2) = \int_x^1 dz \int d^2k_t \ \hat{\sigma}_j(x,Q^2,z,k_t) \ \mathscr{A}\left(z,k_t,\mu_F^2\right)$ (28) where first $\tilde{\sigma}(x',Q^2)$ is calculated numerically with a Monte Carlo integration on a grid in x for the values of Q^2 used in

927

the fit. Then the last step in Eq. 30 is performed with a fast numerical gauss integration, which can be used in standard fit procedures.

Functional Forms for TMD parametrisation: For the starting distribution \mathcal{A}_0 , at the starting scale Q_0^2 , the following form is used:

$$x\mathscr{A}_0(x,k_t) = Nx^{-B}(1-x)^C (1-Dx+E\sqrt{x}) \exp[-k_t^2/\sigma(x,k_t)]$$

with $\sigma^2 = Q_0^2/2$ and the free parameters N, B, C, D, E. Valence quarks are treated using the method of Ref. [122] as described in Ref. [123] with a starting distribution taken from any collinear PDF and imposing the flavor sum rule at every scale p.

The TMD parton densities can be plotted either with HERAFitter

provided tools or with TMDplotter [39].

7 HERAFitter Code Organisation

loaded from the dedicated webpage [1] together with its sup- 941 inclusive [40, 130] and heavy flavour production measureporting documentation and fast grid theory files (described 942 ments [131, 132]. The following phenomenological studin section 4) associated with data files. The source code 943 ies have been performed with HERAFitter: a determination contains all the relevant information to perform QCD fits 944 of the transverse momentum dependent gluon density ustime depends on the fitting options and varies from 10 min- 946 within a dipole model [100], the study of the low-x uncerutes (using "FAST" techniques as described in section 4) 947 tainties in PDFs determined from the HERA data using difto several hours when full uncertainties are estimated. The 948 ferent parametrisations [87] and the impact of QED radiative HERAFitter code is a combination of C++ and Fortran 949 corrections on PDFs [133]. A recent study based on a set of 77 libraries with minimal dependencies, i.e. for the default 950 PDFs determined with the HERAFitter and addressing the fitting options no external dependencies are required except 951 correlated uncertainties between different orders has been the QCDNUM evolution program [26] and CERN libraries. The 952 published in [94]. ROOT libraries are only required for the drawing tools and 953 when invoking APPLGRID. Drawing tools inbuilt in HERAFitter PDF grids from QCD analyses performed at HERA [40, provide a qualitative and quantitative assessment of the re- 955 134] and at the LHC [135], using measurements from ATsults. Fig. 8 shows an illustration of a comparison between 956 LAS [86, 129]. These PDFs can be used to study predictions the inclusive NC data from HERA I with the predictions 957 for SM or beyond SM processes. Furthermore, HERAFitter based on HERAPDF1.0 PDFs. The consistency of the mea- 958 provides the possibility to perform various benchmarking surements and the theory can be expressed by pulls, defined 959 exercises [136] and impact studies for possible future colas the difference between data and theory divided by the un- 960 liders as demonstrated by QCD studies at the LHeC [137]. correlated error of the data. In each kinematic bin of the measurement, pulls are provided in units of standard deviation (sigma). The pulls are also illustrated in Fig. 8.

In HERAFitter there are also available cache options, fast evolution kernels, and the OpenMP (Open Multi-Processing) ies of the structure of the proton. It provides a unique and interface which allows parallel applications of the GM-VFNS theory predictions in DIS. In addition, the HERAFitter references and GNU public licence are provided together with the main source code.

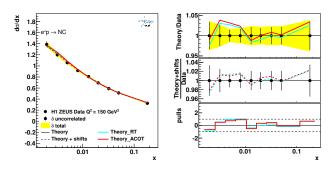

Fig. 8 An illustration of the consistency of HERA measurements [40] and the theory predictions, obtained in HERAFitter with the default drawing tool.

934 8 Applications of HERAFitter

The HERAFitter program has been used in a number of 936 experimental and theoretical analyses. This list includes several LHC analyses of SM processes, namely inclusive Drell-938 Yan and Wand Z production [86, 125–128], and inclusive 939 jet production [129]. The results of QCD analyses using HERAFitter is an open source code and it can be down- 940 HERAFitter were also published by HERA experiments for with HERA DIS data as a default set 1.
