where the cross section σ is expressed as a convolution of Parton Distribution Functions (PDFs) f_a and f_b with the parton cross section $\hat{\sigma}^{ab}$, involving a momentum transfer qsuch that $Q^2 = |q^2| \gg \Lambda_{QCD}^2$, where Λ_{QCD} is the QCD scale. At Leading-Order (LO) in the perturbative expansion of the strong-coupling constant, the gPDFs represent the probability of finding a specific parton a(b) in the first (second) hadron carrying a fraction x_1 (x_2) of its momentum. The indices a and b in Eq. 1 indicate the various kinds of partons, i.e. gluons, quarks and antiquarks of different flavours that are considered as the constituents of the proton. The PDFs depend on the factorisation scale, μ_F , while the parton cross sections depend on the strong coupling constant, α_s , and the factorisation and renormalisation scales, μ_F and μ_R . The parton cross sections $\hat{\sigma}^{ab}$ are calculable in perturbative QCD (pQCD) whereas PDFs are non-perturbative and are usually constrained by global fits to a variety of experimental data. 97 Data: Measurements from various processes are provided The assumption that PDFs are universal, within a particu- 98 in the HERAFitter package including the information on lar factorisation scheme [3-7], is crucial to this procedure. 99 their uncorrelated and correlated uncertainties. 11 number of the existing methods and schemes used for PDF 54 partons. Measurements of inclusive Neutral Current (NC) which are providing predictions for more complex processes at increasingly higher orders, has motivated the development of a tool to combine them together in a fast, efficient, opensource framework.

This paper describes the open-source QCD fit frame-69 work HERAFitter [10], which includes a set of tools to fa-The recent discovery of the Higgs boson [1, 2] and the ex- 70 cilitate global QCD analyses of pp, $p\bar{p}$ and ep scattering data. It has been developed for the determination of PDFs proton collisions demand high-precision calculations to test 72 and the extraction of fundamental parameters of QCD such as the heavy quark masses and the strong coupling constant. 14 It also provides a common framework for the comparison of different theoretical approaches. Furthermore, it can be used to test the impact of new experimental data on the PDFs and on the SM parameters.

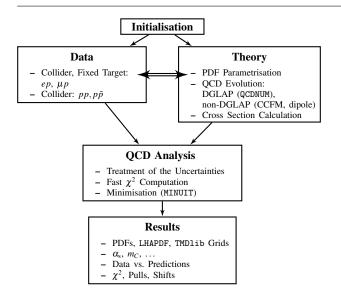

This paper is organised as follows: The general structure of HERAFitter is presented in Sec. 2. In Sec. 3 the various processes available in HERAFitter and the corresponding theoretical calculations, performed within the framework of collinear factorisation and the DGLAP [11–15] formalism, are discussed. In Sec. 4 tools for fast calculations of the theoretical predictions are presented. In Sec. 5 the methodology to determine PDFs through fits based on various χ^2 86 definitions is described. In particular, different treatments of 87 correlated experimental uncertainties are presented. Alter-88 native approaches to the DGLAP formalism are presented 89 in Sec. 6. The organisation of the HERAFitter code is dis-90 cussed in Sec. 7, specific applications of the package are 91 persented in Sec. 8, which is followed by a summary in

2 The HERAFitter Structure

71

⁹⁴ The diagram in Fig. 1 gives a schematic overview of the 95 HERAFitter structure and functionality, which can be di-96 vided into four main blocks:

A precise determination of PDFs as a function of x re- 101 PDFs through scaling violations and the longitudinal strucquires large amounts of experimental data that cover a wide $_{102}$ ture function F_L . These data are the basis of any proton PDF 53 kinematic region and that are sensitive to different kinds of 103 extraction, and are used in all current PDF sets from MSTW

104 [16], CT [17], NNPDF [18], ABM [19], JR [20] and HERA-PDF [21] groups. Measurements of charm and beauty quark production at HERA are sensitive to heavy quark PDFs, jet measurements have direct sensitivity to the gluon PDF. However, the kinematic range of HERA data mostly covers low and medium ranges in x. Measurements from the fixed target experiments, the Tevatron and the LHC provide additional constraints on the gluon and quark distributions at high-x, 138 the distributions of the systematic uncertainties, e.g. Gausbetter understanding of heavy quark distributions and de- 139 sian or LogNormal [32], can also be studied (see Sec. 5.3). composition of the light-quark sea. For these purposes, measurements from fixed-target experiments, the Tevatron and the LHC can be used.

Fitter framework are listed in Tab. 1.

PDFs are evolved to the scale of the measurement \hat{Q}^2 , $Q^2 > 146$ Ref. [21]). Note that following conventions, the PDFs are Q_0^2 . By default, the evolution uses the DGLAP formalism ¹⁴⁷ displayed as parton momentum distributions $xf(x,\mu_F^2)$. [11–15] as implemented in QCDNUM [22]. Alternatively, the CCFM evolution [23–26] as implemented in uPDFevolv [27] can be chosen. The prediction of the cross section for a par- 148 3 Theoretical formalism using DGLAP evolution ticular process is obtained, assuming factorisation, by the convolution of the evolved PDFs with the corresponding 149 In this section the theoretical formalism based on DGLAP parton scattering cross section. 140 Results: The resulting PDFs are provided in a format ready The processes that are currently available within the HERA¹⁴¹ to be used by the LHAPDF library [33, 34] or by TMDlib [35]. HERAFitter drawing tools can be used to display the PDFs with their uncertainties at a chosen scale. As an example, the Theory: The PDFs are parametrised at a starting scale, Q_0^2 , 144 first set of PDFs extracted using HERAFitter from HERA using a functional form and a set of free parameters p. These 145 I data, HERAPDF1.0 [21], is shown in Fig. 2 (taken from

A direct consequence of factorisation (Eq. 1) is that the scale dependence or "evolution" of the PDFs can be predicted by the renormalisation group equations. By requiring QCD Analysis: The PDFs are determined in a least squares physical observables to be independent of μ_F , a representafit: a χ^2 function, which compares the input data and theory 155 tion of the parton evolution in terms of the DGLAP equa-

$$\frac{d f_a(x, \mu_F^2)}{d \log \mu_F^2} = \sum_{b=a\bar{a}, \rho} \int_x^1 \frac{dz}{z} P_{ab} \left(\frac{x}{z}; \mu_F^2\right) f_b(z, \mu_F^2), \qquad (2)$$

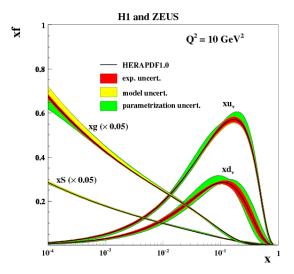

Fig. 2 Distributions of valence (xu_v, xd_v) , sea (xS) and the gluon (g)PDFs in HERAPDF1.0 [21]. The gluon and the sea distributions are scaled down by a factor of 20. The experimental, model and parametrisation uncertainties are shown as coloured bands.

where the functions P_{ab} are the evolution kernels or splitting functions, which represent the probability of parton a to evolve into parton b. They can be calculated as a perturbative expansion in α_s . Once PDFs are determined at the initial scale $\mu_F^2 = Q_0^2$, their evolution to any other scale $Q^2 > Q_0^2$ is entirely determined by the DGLAP equations. The PDFs are then used to calculate cross sections for various different processes. Alternative approaches to DGLAP evolution equations, valid in different kinematic regimes, are also implemented in HERAFitter and will be discussed in Sec. 6.

3.1 Deep Inelastic Scattering and Proton Structure

The formalism that relates the DIS measurements to pOCD and the PDFs has been described in detail in many extensive reviews (see e.g. Ref. [36]) and it is only briefly summarised here. DIS is the process where a lepton scatters off the partons in the proton by a virtual exchanged of a neu- 216 Zero-Mass Variable Flavour Number (ZM-VFN): tral (γ/Z) or charged (W^{\pm}) vector boson and, as a result, a 217 In this scheme [37], the heavy quarks appear as partons in scattered lepton and a hadronic final state are produced. The 218 the proton at Q^2 values above $\sim m_h^2$ (heavy quark mass) and common DIS kinematic variables are the scale of the pro- 219 they are then treated as massless in both the initial and ficess Q^2 , which is the absolute squared four-momentum of 220 nal states of the hard scattering process. The lowest order the exchange boson, Bjorken x, which can be related in the 221 process is the scattering of the lepton off the heavy quark parton model to the momentum fraction that is carried by 222 via electroweak boson exchange. This scheme is expected the struck quark, and the inelasticity y. These are related by $_{223}$ to be reliable in the region where $Q^2\gg m_h^2$. In HERAFitter $y = Q^2/sx$, where s is the squared centre-of-mass (c.o.m.) 224 this scheme is available for the DIS structure function cal-

The NC cross section can be expressed in terms of gener- 226 it benefits from the fast QCDNUM convolution engine.

alised structure functions:

$$\frac{d^2 \sigma_{NC}^{e^{\pm} p}}{dx dQ^2} = \frac{2\pi \alpha^2 Y_+}{x Q^4} \sigma_{r,NC}^{e^{\pm} p},\tag{3}$$

$$\sigma_{r,NC}^{e^{\pm}p} = \tilde{F}_2^{\pm} \mp \frac{Y_-}{Y_+} x \tilde{F}_3^{\pm} - \frac{y^2}{Y_+} \tilde{F}_L^{\pm}, \tag{4}$$

where $Y_{\pm} = 1 \pm (1 - y)^2$ and α is the electromagnetic coupling constant. The generalised structure functions $\tilde{F}_{2,3}$ can be written as linear combinations of the proton structure functions F_2^{γ} , $F_{2,3}^{\gamma Z}$ and $F_{2,3}^{Z}$, which are associated with pure photon exchange terms, photon-Z interference terms and pure Z exchange terms, respectively. The structure function \tilde{F}_2 is the dominant contribution to the cross section, $x\tilde{F}_3$ becomes important at high Q^2 and \tilde{F}_L is sizable only at high y. In the framework of pQCD, the structure functions are directly related to the PDFs: at LO F_2 is the weighted momentum sum of quark and anti-quark distributions, xF_3 is related to their difference, and F_L vanishes. At higher orders, terms related to the gluon distribution appear, in particular F_L is strongly related to the low-*x* gluon.

The inclusive CC ep cross section, analogous to the NC ep case, can be expressed in terms of another set of structure 200 functions, \tilde{W} :

$$\frac{d^2 \sigma_{CC}^{e^{\pm} p}}{dx dQ^2} = \frac{1 \pm P}{2} \frac{G_F^2}{2\pi x} \left[\frac{m_W^2}{m_W^2 + Q^2} \right] \sigma_{r,CC}^{e^{\pm} p}$$
 (5)

$$\sigma_{r,CC}^{e^{\pm}p} = Y_{+}\tilde{W}_{2}^{\pm} \mp Y_{-}x\tilde{W}_{3}^{\pm} - y^{2}\tilde{W}_{L}^{\pm}, \tag{6}$$

where P represents the lepton beam polarisation. At LO in α_s , the CC e^+p and e^-p cross sections are sensitive to different combinations of the quark flavour densities.

Beyond LO, the OCD predictions for the DIS structure functions are obtained by convoluting the PDFs with appropriate hard-process scattering matrix elements, which are referred to as coefficient functions.

The DIS measurements span a large range of Q^2 from a few GeV² to about 10⁵ GeV², crossing heavy quark mass 210 thresholds, thus the treatment of heavy quark (charm and 211 beauty) production and the chosen values of their masses 212 become important. There are different schemes for the treat-213 ment of heavy quark production. Several variants of these 214 schemes are implemented in HERAFitter and they are briefly 215 discussed below.

225 culation via the interface to the QCDNUM [22] package, thus

Fixed Flavour Number (FFN):

In this rigorous quantum field theory scheme [38–40], only 279 the gluon and the light quarks are considered as partons 280 within the proton and massive quarks are produced pertur- 281 batively in the final state. The lowest order process is the 282 heavy quark-antiquark pair production via boson-gluon fu- 283 sion. In HERAFitter this scheme can be accessed via the 284 QCDNUM implementation or through the interface to the opensource code OPENQCDRAD [41] as implemented by the ABM group. This scheme is reliable for $Q^2 \sim m_h^2$. In QCDNUM, the calculation of the heavy quark contributions to DIS structure functions are available at Next-to-Leading Order (NLO) and only electromagnetic exchange contributions are taken into account. In the OPENQCDRAD implementation the heavy quark contributions to CC structure functions are also available and, for the NC case, the QCD corrections to the coefficient functions in Next-to-Next-to Leading Order (NNLO) are provided in the best currently known approximation [42]. The OPENQCDRAD implementation uses in addition the running heavy quark mass in the \overline{MS} scheme [43].

It is sometimes argued that this scheme reduces the sensitivity of the DIS cross sections to higher order corrections [42]. It is also known to have smaller non-perturbative corrections than the pole mass scheme [44].

General-Mass Variable Flavour Number (GM-VFN):

In this scheme [45], heavy quark production is treated for $Q^2 \sim m_h^2$ in the FFN scheme and for $Q^2 \gg m_h^2$ in the massless scheme with a suitable interpolation in between. The details of this interpolation differ between implementations. The groups that use GM-VFN schemes in PDFs are MSTW. CT (CTEQ), NNPDF, and HERAPDF. HERAFitter implements different variants of the GM-VFN scheme.

GM-VFN Thorne-Roberts scheme: The Thorne-Roberts (TR) scheme [46] was designed to provide a smooth transition from the massive FFN scheme at low scales difficult to implement beyond NLO, it was updated to the TR' scheme [47]. There are two variants of the TR' schemes: TR' standard (as used in MSTW PDF sets [16, 47]) and TR' optimal [48], with a smoother transition across the heavy quark threshold region. Both TR' variants are accessible within the HERAFitter package at LO, NLO and NNLO.

263

276

GM-VFN ACOT scheme: The Aivazis-Collins-Olness- 295 3.3 Diffractive PDFs Tung (ACOT) scheme belongs to the group of VFN fac-

of the ACOT scheme are available: ACOT-Full [50], S-ACOT- χ [51, 52], ACOT-ZM [50], $\overline{\text{MS}}$ at LO and NLO. For the longitudinal structure function higher order calculations are also available. A comparison of PDFs extracted from QCD fits to the HERA data with the TR' and ACOT-Full schemes is illustrated in Fig. 3 (taken from [21]).

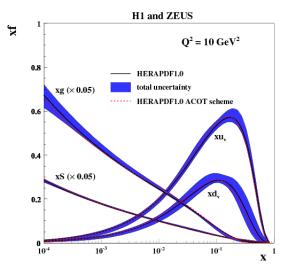

Fig. 3 Distributions of valence (xu_v, xd_v) , sea (xS) and the gluon (g)PDFs in HERAPDF1.0 [21] with their total uncertainties at the scale of $Q^2 = 10 \text{ GeV}^2$ obtained using the TR' scheme and compared to the PDFs obtained with the ACOT-Full scheme using the k-factor technique (red). The gluon and the sea distributions are scaled down by a factor of 20.

3.2 Electroweak Corrections to DIS

286 Calculations of higher-order electroweak corrections to DIS at HERA are available in HERAFitter in the on-shell scheme $Q^2 \sim m_h^2$ to the massless ZM-VFNS scheme at high scales $Q^2 \gg m_h^2$. Because the original version was technically m_{Z} are treated as basic parameters together with the top $_{289}$ m_Z are treated as basic parameters together with the top, 290 Higgs and fermion masses. These electroweak corrections ²⁹¹ are based on the EPRC package [53]. The code calculates the running of the electromagnetic coupling α using the most recent parametrisation of the hadronic contribution [54] as well as an older version from Burkhard [55].

torisation schemes that use the renormalisation method 296 About 10% of deep inelastic interactions at HERA are diffracof Collins-Wilczek-Zee (CWZ) [49]. This scheme uni- 297 tive, such that the interacting proton stays intact $(ep \to eXp)$. fies the low scale $Q^2 \sim m_h^2$ and high scale $Q^2 > m_h^2$ re- 298 The proton is well separated from the rest of the hadronic figions in a coherent framework across the full energy 299 nal state by a large rapidity gap. This is interpreted as the range. Within the ACOT package, the following variants 300 dissociation of the virtual photon into a hadronic system X

with a squared invariant mass much smaller than the photon- 330 proton c.o.m. energy $W^2 = ys - Q^2 + m_p^2(1-y)$, where m_p 331 variant mass m, boson rapidity y and lepton scattering angle is the proton mass. Such a process is often assumed to be $332 \cos \theta$ in the parton c.o.m. frame can be written as [60, 61]: mediated by the exchange of a hard Pomeron or a secondary Reggeon with vacuum quantum numbers. This factorisable Pomeron picture has proved remarkably successful in the description of most of the diffractive data. Diffractive parton distributions (DPDFs) can be determined from QCD fits to diffractive cross sections in a similar way to the determination of the standard PDFs [56].

In addition to the usual DIS variables x, Q^2 , extra kinematic variables are needed to describe the diffractive process. These are the squared four-momentum transfer of the 337 exchanged Pomeron or Reggeon, t, and the mass m_X of the 338 The corresponding triple differential CC cross section has diffractively produced final state. In practice, the variable 339 the form: m_X is often replaced by the dimensionless quantity $\beta = \frac{Q^2}{m_X^2 + Q^2 - t}$. $\frac{d^3\sigma}{dmdyd\cos\theta} = \frac{\pi\alpha^2}{48s\sin^4\theta_W} \frac{m^3(1-\cos\theta)^2}{(m^2 - m_W^2) + \Gamma_W^2 m_W^2}$ at LO as the fraction of the Pomeron longitudinal momentum. $\sum_{q_1,q_2} V_{q_1q_2}^2 f_{q_1}(x_1,m^2) f_{q_2}(x_2,m^2)$, then we which is carried by the struck parton $x = \beta xm$ tum, x_{IP} , which is carried by the struck parton, $x = \beta x_{IP}$, where *P* denotes the momentum of the proton.

$$\frac{d^4\sigma}{d\beta dQ^2 dx_{IP} dt} = \frac{2\pi\alpha^2}{\beta Q^4} \left(1 + (1-y)^2 \right) \overline{\sigma}^{D(4)}(\beta, Q^2, x_{IP}, t) \tag{7}$$

with the "reduced cross section":

$$\overline{\sigma}^{D(4)} = F_2^{D(4)} - \frac{y^2}{1 + (1 - y)^2} F_L^{D(4)}.$$
 (8)

The diffractive structure functions can be expressed as convolutions of calculable coefficient functions with the diffração tive quark and gluon distribution functions, which in general depend on x_{IP} , Q^2 , β and t.

mented as a sum of two factorised contributions:

$$\Phi_{IP}(x_{IP},t) f_a^{IP}(\beta,Q^2) + \Phi_{IR}(x_{IP},t) f_a^{IR}(\beta,Q^2),$$
 (9)

3.4 Drell-Yan Processes in pp or $p\bar{p}$ Collisions

The Drell-Yan (DY) process provides valuable information about PDFs. In pp and $p\bar{p}$ scattering, the Z/γ^* and W pro- $_{362}$ 3.5 Jet Production in ep and pp or $p\bar{p}$ Collisions duction probe bi-linear combinations of quarks. Complementary information on the different quark densities can be $_{363}$ The cross section for production of high p_T hadronic jets obtained from the W^{\pm} asymmetry (d, u and their ratio), the 364 is sensitive to the high-x gluon PDF (see e.g. Ref. [16]). ratio of the W and Z cross sections (sensitive to the flavour 365 Therefore this process can be used to improve the determicomposition of the quark sea, in particular to the s-quark 366 nation of the gluon PDF, which is particularly important for distribution), and associated W and Z production with heavy 367 Higgs production and searches for new physics. Jet producquarks (sensitive to c- and b-quark densities). Measurements 368 tion cross sections are currently known only to NLO. Calcuat large boson transverse momentum $p_T \gtrsim m_{W,Z}$ are poten- 369 lations for higher-order contributions to jet production in pptially sensitive to the gluon distribution [59].

At LO the DY NC cross section triple differential in in-

$$\frac{d^3\sigma}{dmdyd\cos\theta} = \frac{\pi\alpha^2}{3ms} \sum_{q} \hat{\sigma}^q(\cos\theta, m) \times \left[f_q(x_1, m^2) f_{\bar{q}}(x_2, m^2) + (q \leftrightarrow \bar{q}) \right], \quad (10)$$

where s is the squared c.o.m. beam energy, the parton momentum fractions are given by $x_{1,2} = \frac{m}{\sqrt{s}} \exp(\pm y)$, $f_q(x_1, m^2)$ are the PDFs at the scale of the invariant mass, and $\hat{\sigma}^q$ is the parton-parton hard scattering cross section.

$$\frac{d^{3}\sigma}{dmdyd\cos\theta} = \frac{\pi\alpha^{2}}{48s\sin^{4}\theta_{W}} \frac{m^{3}(1-\cos\theta)^{2}}{(m^{2}-m_{W}^{2}) + \Gamma_{W}^{2}m_{W}^{2}} \times \sum_{q_{1},q_{2}} V_{q_{1}q_{2}}^{2} f_{q_{1}}(x_{1},m^{2}) f_{q_{2}}(x_{2},m^{2}), \tag{11}$$

where $V_{q_1q_2}$ is the Cabibbo-Kobayashi-Maskawa (CKM) quark For the inclusive case, the diffractive cross section reads as: $_{341}$ mixing matrix and m_W and Γ_W are the W boson mass and decay width, respectively.

> The simple LO form of these expressions allows for the analytic calculations of integrated cross sections. In both NC and CC expressions the PDFs depend only on the boson ra-(8) 346 pidity y and invariant mass m, while the integral in $\cos \theta$ can 347 be evaluated analytically even for the case of realistic kine-348 matic cuts.

Beyond LO, the calculations are often time-consuming and Monte Carlo generators are often employed. Currently, the predictions for W and Z/γ^* production are available up The diffractive PDFs [57, 58] in HERAFitter are imple- $_{352}$ to NNLO and the predictions for W, Z in association with 353 heavy flavour quarks is available to NLO.

There are several possibilities to obtain the theoretical predictions for DY production in HERAFitter. The NLO where $\Phi(x_{I\!P},t)$ are the Reggeon and Pomeron fluxes. The 356 and NNLO calculations are time consuming and k-factor or ₃₅₉ 64], available for NLO calculations, or FEWZ [65] and DYNNLO[66] 360 for NLO and NNLO, with electroweak corrections estimated 361 using MCSANC [67, 68].

450 4.2 Fast Grid Techniques

Fast grid techniques exploit the fact that iterative PDF fit-452 ting procedures do not impose completely arbitrary changes 453 to the types and shapes of the parameterised functions that represent each PDF. Instead, it can be assumed that a generic 455 PDF can be approximated by a set of interpolating func-456 tions with a sufficient number of judiciously chosen sup-Precise measurements require accurate theoretical predic- 457 port points. The accuracy of this approximation is checked tions in order to maximise their impact in PDF fits. Perturba- 458 and optimised such that the approximation bias is negligibly tive calculations become more complex and time-consuming 459 small compared to the experimental and theoretical accuat higher orders due to the increasing number of relevant 460 racy. This method can be used to perform the time consum-Feynman diagrams. The direct inclusion of computationally 461 ing higher-order calculations (Eq. 1) only once for the set of demanding higher-order calculations into iterative fits is thus 462 interpolating functions. Further iterations of the calculation not possible currently. However, a full repetition of the per- 463 for a particular PDF set are fast, involving only sums over turbative calculation for small changes in input parameters 464 the set of interpolators multiplied by factors depending on is not necessary at each step of the iteration. Two methods 465 the PDF. This approach can be used to calculate the cross have been developed which take advantage of this to solve 466 sections of processes involving one or two hadrons in the the problem: the k-factor technique and the fast grid tech- 467 initial state and to assess their renormalisation and factori-468 sation scale variation.

This technique was pioneered by the fastNLO project [85]22 to facilitate the inclusion of time consuming NLO jet cross 523 section predictions into PDF fits. The APPLGRID [86] project 524 developed an alternative method and, in addition to jets, ex- 525 tended its applicability to other scattering processes, such 526 as DY and heavy quark pair production in association with 527 boson production. The packages differ in their interpolation 528 and optimisation strategies, but both of them construct ta- 529 bles with grids for each bin of an observable in two steps: 530 in the first step, the accessible phase space in the parton mo- 531 mentum fractions x and the renormalisation and factorisa- 532 tion scales μ_R and μ_F is explored in order to optimise the table size. In the second step the grid is filled for the requested observables. Higher-order cross sections can then be obtained very efficiently from the pre-produced grids while varying externally provided PDF sets, μ_R and μ_F , or the strong coupling $\alpha_s(\mu_R)$. This approach can in principle be extended to arbitrary processes. This requires an interface between the higher-order theory programs and the fast interpolation frameworks. Currently available processes for each package are as follows:

The fastNLO project [85] has been interfaced to the NLOJet++ program [72] for the calculation of jet production in DIS [87] as well as 2- and 3-jet production in hadron-hadron collisions at NLO [73, 88]. Threshold corrections at 2-loop order, which approximate the NNLO for the inclusive jet cross section, have also been included into the framework [89] following Ref. [90]. The latest version of the fastNLO convolution program [91] allows for the creation of tables in which renormalisation and factorisation scales can be varied as a function of two pre-defined observables, e.g. jet transverse momentum p_{\perp} and Q for DIS. Recently, the differential calculation of top-pair production in hadron collisions at approximate NNLO [82] has been interfaced to fastNLO [84]. The fastNLO code is available online [92]. Jet cross section grids computed for the kinematics of various experiments can be downloaded from this 533 5 Fit Methodology

ori, when calculating theory predictions with the APPL- 547 to treat data and their uncertainties.

GRID tables, and independent variation of α_S is also allowed. For higher-order predictions, the k-factors technique can also be applied within the APPLGRID framework.

As an example, the HERAFitter interface to APPLGRID was used by the ATLAS [94] and CMS [95] collaborations to extract the strange quark distribution of the proton. The ATLAS strange PDF extracted employing these techniques is displayed in Fig. 4 together with a comparison to the global PDF sets CT10 [17] and NNPDF2.1 [18] (taken from [94]).

5.1 Functional Forms for PDF Parametrisation

The PDFs can be parametrised using several predefined functional forms and flavour decompositions:

Standard Polynomials: The standard polynomial form is the most commonly used. A polynomial functional form is used to parametrise the x-dependence of the PDFs, where index j denotes each parametrised PDF flavour:

$$xf_{j}(x) = A_{j}x^{B_{j}}(1-x)^{C_{j}}P_{j}(x).$$
(12)

The parametrised PDFs are the valence distributions xu_y and xd_v , the gluon distribution xg, and the u-type and d-type sea, $x\bar{U}$, $x\bar{D}$, where $x\bar{U} = x\bar{u}$, $x\bar{D} = x\bar{d} + x\bar{s}$ at the starting scale, which is chosen below the charm mass threshold. The form of polynomials $P_i(x)$ can be varied. The form $(1 + \varepsilon_i \sqrt{x} +$ $D_i x + E_i x^2$) is used for the HERAPDF [21] with additional constraints relating to the flavour decomposition of the light sea. This parametrisation is termed HERAPDF-style. The polynomial can also be parametrised in the CTEQ-style, where $P_i(x)$ takes the form $e^{a_3x}(1+e^{a_4}x+e^{a_5}x^2)$ and, in contrast to the HERAPDF-style, this is positive by construction. QCD number and momentum sum rules are used to determine the normalisations A for the valence and gluon distributions, and the sum-rule integrals are solved analytically.

Bi-Log-Normal Distributions: This parametrisation is motivated by multi-particle statistics and has the following functional form:

$$xf_j(x) = a_j x^{p_j - b_j \log(x)} (1 - x)^{q_j - d_j \log(1 - x)}.$$
 (13)

This function can be regarded as a generalisation of the standard polynomial form described above, however, numerical integration of Eq. 13 is required in order to impose the QCD sum rules.

Chebyshev Polynomials: A flexible parametrisation based on the Chebyshev polynomials can be employed for the gluon the drawing tools available in HERAFitter. and sea distributions. Polynomials with argument log(x) are considered for better modelling the low-x asymptotic behaviour of those PDFs. The polynomials are multiplied by resulting parametric form reads

$$xg(x) = A_g (1-x) \sum_{i=0}^{N_g-1} A_{g_i} T_i \left(-\frac{2\log x - \log x_{\min}}{\log x_{\min}} \right), \quad (14)$$

$$xS(x) = (1-x)\sum_{i=0}^{N_S-1} A_{S_i} T_i \left(-\frac{2\log x - \log x_{\min}}{\log x_{\min}} \right),$$
 (15)

In this section we describe the available options for the sal where T_i are first-type Chebyshev polynomials of order i. polynomial parametrisation from $N_{g,S} \ge 5$ and has a similar number of free parameters. Fig. 5 (taken from [96]) shows ⁵⁸⁷ a comparison of the gluon distribution obtained with the parametrisation Eqs. 14, 15 to the standard-polynomial one, for $N_{g,S} = 9$.

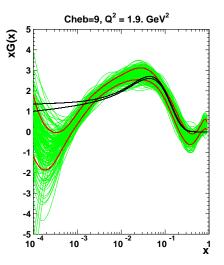

Fig. 5 The gluon density is shown at the starting scale $Q^2 = 1.9 \text{ GeV}^2$. The black lines correspond to the uncertainty band of the gluon distribution using a standard parametrisation and it is compared to the case of the Chebyshev parametrisation [96]. The uncertainty band for the latter case is estimated using the Monte Carlo technique (see Sec. 5.3) with the green lines denoting fits to data replica. Red lines indicate the standard deviation about the mean value of these replicas.

590 External PDFs: HERAFitter also provides the possibility (13) 591 to access external PDF sets, which can be used to compute theoretical predictions for the cross sections for all the pro-593 cesses available in HERAFitter. This is possible via an in-594 terface to LHAPDF [33, 34] providing access to the global PDF sets. HERAFitter also allows one to evolve PDFs from 596 LHAPDF using QCDNUM. Fig. 6 illustrates a comparison of various gluon PDFs accessed from LHAPDF as produced with

Covariance Matrix Representation: For a data point μ_i with 646 a corresponding theory prediction m_i , the χ^2 function can be expressed in the following form:

$$\chi^{2}(m) = \sum_{i,k} (m_{i} - \mu_{i}) C_{ik}^{-1}(m_{k} - \mu_{k}), \tag{16}$$

variance matrix C_{ik} for measurements in bins i and k. The viewed here: the Hessian, Offset, and Monte Carlo method. covariance matrix C_{ik} is given by a sum of statistical, uncorrelated and correlated systematic contributions:

$$C_{ik} = C_{ik}^{stat} + C_{ik}^{uncor} + C_{ik}^{sys}. \tag{17}$$

Using this representation one cannot distinguish the ef- 654 fect of each source of systematic uncertainty.

Nuisance Parameter Representation: In this case, the χ^2 is expressed as

$$\chi^{2}(m,b) = \sum_{i} \frac{\left[\mu_{i} - m_{i} \left(1 - \sum_{j} \gamma_{j}^{i} b_{j}\right)\right]^{2}}{\delta_{i,\text{unc}}^{2} m_{i}^{2} + \delta_{i,\text{stat}}^{2} \mu_{i} m_{i} \left(1 - \sum_{j} \gamma_{j}^{i} b_{j}\right)} + \sum_{j} b_{j}^{2},$$
(18)

where, $\delta_{i, \text{stat}}$ and $\delta_{i, \text{unc}}$ are relative statistical and uncorrelated systematic uncertainties of the measurement i. 666 Further, γ_i^i quantifies the sensitivity of the measurement 667 to the correlated systematic source j. The function χ^2 668 depends on the set of systematic nuisance parameters b_i . 669 This definition of the χ^2 function assumes that systematic uncertainties are proportional to the central predic- 671 tion values (multiplicative uncertainties, $m_i(1-\sum_j \gamma_i^j b_j)$), 672 whereas the statistical uncertainties scale with the square 673 root of the expected number of events. However, additive treatment of uncertainties is also possible in HERA-Fitter.

625

629

631

633

634

635

638

During the χ^2 minimisation, the nuisance parameters b_j and the PDFs are determined, such that the effect of different sources of systematic uncertainties can be distin-

Mixed Form Representation: In some cases, the statistical and systematic uncertainties of experimental data are provided in different forms. For example, the correlated experimental systematic uncertainties are available as nuisance parameters, but the bin-to-bin statistical correlations are given in the form of a covariance matrix. HERA-Fitter offers the possibility to include such mixed forms of information.

Any source of measured systematic uncertainty can be treated as additive or multiplicative, as described above. The statistical uncertainties can be included as additive or following the Poisson statistics. Minimisation with respect to nuisance parameters is performed analytically, however, for more detailed studies of correlations individual nuisance parameters can be included into the MINUIT minimisation.

$(16)^{-647}$ 5.3 Treatment of the Experimental Uncertainties

Three distinct methods for propagating experimental uncerwhere the experimental uncertainties are given as a co- 649 tainties to PDFs are implemented in HERAFitter and re-

> Hessian (Eigenvector) method: The PDF uncertainties reflecting the data experimental uncertainties are estimated by examining the shape of the χ^2 function in the neighbourhood of the minimum [97]. Following the approach of Ref. [97], the Hessian matrix is defined by the second derivatives of χ^2 on the fitted PDF parameters. The matrix is diagonalised and the Hessian eigenvectors are computed. Due to orthogonality these vectors correspond to independent sources of uncertainty in the obtained PDFs.

> Offset method: The Offset method [98] uses the χ^2 function for the central fit, but only uncorrelated uncertainties are taken into account. The goodness of the fit can no longer be judged from the χ^2 since correlated uncertainties are ignored. The correlated uncertainties are propagated into the PDF uncertainties by performing variants of the fit with the experimental data varied by $\pm 1\sigma$ from the central value for each systematic source. The resulting deviations of the PDF parameters from the ones obtained in the central fit are statistically independent, and they can be combined in quadrature to derive a total PDF systematic uncertainty.

The uncertainties estimated by the offset method are gen-702 erally larger than those from the Hessian method.

700

Monte Carlo method: The Monte Carlo (MC) technique [99, 100] can also be used to determine PDF uncertainties. The uncertainties are estimated using pseudo-data replicas (typically > 100) randomly generated from the measurement central values and their systematic and statistical uncertainties taking into account all point-to-point correlations. The QCD fit is performed for each replica and the PDF central values and their experimental uncertainties are estimated from the distribution of the PDF parameters obtained in these fits, by taking the mean values and standard deviations over the replicas.

The MC method has been checked against the standard error estimation of the PDF uncertainties obtained by the Hessian method. A good agreement was found between the methods provided that Gaussian distributions of statistical and systematic uncertainties are assumed in the MC approach [32]. A comparison is illustrated in Fig. 7. Similar findings were reported by the MSTW 704 5.4 Treatment of the Theoretical Input Parameters global analysis [101].

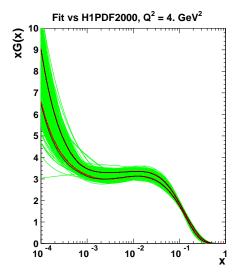

Fig. 7 Comparison between the standard error calculations as employed by the Hessian approach (black lines) and the MC approach $\ensuremath{\,^{721}}$ (with more than 100 replicas) assuming Gaussian distribution for un- 722 further developed by the NNPDF Collaboration [104, 105]. certainty distributions, shown here for each replica (green lines) together with the evaluated standard deviation (red lines) [32]. The black and red lines in the figure are superimposed because agreement of the methods is so good that it is hard to distinguish them.

to store the PDF uncertainties. It is possible to transform 730 mented in HERAFitter. MC to eigenvector representation as shown by [102]. Tools to perform this transformation are provided with HERAFitter and were recently employed for the repre-

sentation of correlated sets of PDFs at different perturbative orders [103].

The nuisance parameter representation of χ^2 in Eq. 18 is derived assuming symmetric experimental errors, however, the published systematic uncertainties are often asymmetric. HERAFitter provides the possibility to use asymmetric systematic uncertainties. The implementation relies on the assumption that asymmetric uncertainties can be described by a parabolic function. The nuisance parameter in Eq. 18 is modified as follows

$$\gamma_i^i \to \omega_i^i b_i + \gamma_i^i,$$
 (19)

where the coefficients ω_i^i , γ_i^i are defined from the maximum and minimum shifts of the cross sections due to a variation of the systematic uncertainty j, S_{ij}^{\pm} ,

$$\omega_{j}^{i} = \frac{1}{2} \left(S_{ij}^{+} + S_{ij}^{-} \right), \qquad \gamma_{j}^{i} = \frac{1}{2} \left(S_{ij}^{+} - S_{ij}^{-} \right).$$
 (20)

The results of a OCD fit depend not only on the input data but also on the input parameters used in the theoretical calculations. Nowadays, PDF groups address the impact of the choices of theoretical parameters by providing alternative PDFs with different choices of the mass of the charm quarks, 710 m_c , mass of the bottom quarks, m_b , and the value of $\alpha_{\rm s}(m_Z)$. Other important aspects are the choice of the functional form for the PDFs at the starting scale and the value of the starting scale itself. HERAFitter provides the possibility of different user choices of all these inputs.

5.5 Bayesian Reweighting Techniques

As an alternative to performing a full QCD fit, HERAFitter 717 allows the user to assess the impact of including new data in an existing fit using the Bayesian Reweighting technique. The method provides a fast estimate of the impact of new data on PDFs. Bayesian Reweighting was first proposed for PDF sets delivered in the form of MC replicas by [99] and More recently, a method to perform Bayesian Reweighting studies starting from PDF fits for which uncertainties are provided in the eigenvector representation has been also developed [101]. The latter is based on generating replica sets by introducing Gaussian fluctuations on the central PDF set Since the MC method requires large number of replicas, 728 with a variance determined by the PDF uncertainty given the eigenvector representation is a more convenient way 729 by the eigenvectors. Both reweighting methods are imple-

> The Bayesian Reweighting technique relies on the fact that MC replicas of a PDF set give a representation of the probability distribution in the space of PDFs. In particular,

the PDFs are represented as ensembles of N_{rep} equiprobable 743 **6 Alternatives to DGLAP Formalism** (i.e. having weights equal to unity) replicas, $\{f\}$. The central value for a given observable, $\mathcal{O}(\{f\})$, is computed as the 744 QCD calculations based on the DGLAP [11-15] evolution average of the predictions obtained from the ensemble as

$$\langle \mathscr{O}(\{f\}) \rangle = \frac{1}{N_{\text{rep}}} \sum_{k=1}^{N_{\text{rep}}} \mathscr{O}(f^k),$$
 (21)

and the uncertainty as the standard deviation of the sample. 751

Upon inclusion of new data the prior probability distribution, given by theoriginal PDF set, is modified according to Bayes Theorem such that the weight of each replica, w_k , is updated according to

$$w_k = \frac{(\chi_k^2)^{\frac{1}{2}(N_{\text{data}} - 1)} e^{-\frac{1}{2}\chi_k^2}}{\frac{1}{N_{\text{rep}}} \sum_{k=1}^{k} (\chi_k^2)^{\frac{1}{2}(N_{\text{data}} - 1)} e^{-\frac{1}{2}\chi_k^2}},$$
(22)

where $N_{\rm data}$ is the number of new data points, k denotes the specific replica for which the weight is calculated and χ_k^2 is the χ^2 of the new data obtained using the k-th PDF replica. Given a PDF set and a corresponding set of weights, which describes the impact of the inclusion of new data, the prediction for a given observable after inclusion of the new data can be computed as the weighted average.

$$\langle \mathcal{O}(\{f\}) \rangle = \frac{1}{N_{\text{rep}}} \sum_{k=1}^{N_{\text{rep}}} w_k \mathcal{O}(f^k).$$
 (23)

To simplify the use of a reweighted set, an unweighted set (i.e. a set of equiprobable replicas which incorporates the information contained in the weights) is generated according to the unweighting procedure described in [104]. The number of effective replicas of a reweighted set is measured by its Shannon Entropy [105]

$$N_{\text{eff}} \equiv \exp\left\{\frac{1}{N_{\text{rep}}} \sum_{k=1}^{N_{\text{rep}}} w_k \ln(N_{\text{rep}}/w_k)\right\},\,$$
(24)

set containing the same amount of information. This num- τ_0 tion σ_0 , τ_0 , and τ_0 are parameters of the model fitted to the ber of effective replicas, $N_{\rm eff}$, gives an indicative measure of TTT DIS data. This model gives exact Bjorken scaling when the the optimal size of an unweighted replica set produced with 778 dipole size r is small. the reweighting/unweighting procedure. No extra information is gained by producing a final unweighted set that has a 779 BGK model: The BGK model is a modification of the GBW number of replicas (significantly) larger than $N_{\rm eff}$. If $N_{\rm eff}$ is 780 model assuming that the spacing R_0 is inverse to the gluon much smaller than the original number of replicas the new 781 distribution and taking into account the DGLAP evolution data have great impact, however, it is unreliable to use the 782 of the latter. At small-x and small- Q^2 DGLAP dynamics may be modi-(21) 748 fied by saturation and other (non-perturbative) higher-twist effects. Different approaches alternative to the DGLAP formalism can be used to analyse DIS data in HERAFitter. These include several dipole models and the use of transverse momentum dependent, or unintegrated PDFs (uPDFs).

753 6.1 Dipole Models

The dipole picture provides an alternative approach to proton-(22) 755 virtual photon scattering at low x which can be applied to both inclusive and diffractive processes. In this approach, the virtual photon fluctuates into a $q\bar{q}$ (or $q\bar{q}g$) dipole which interacts with the proton [106, 107]. The dipoles can be considered as quasi-stable quantum mechanical states, which have very long life time $\propto 1/m_p x$ and a size which is not 761 changed by scattering with the proton. The dynamics of the interaction are embedded in a dipole scattering amplitude.

Several dipole models, which assume different behaviours of the dipole-proton cross section, are implemented in HERA-765 Fitter: the Golec-Biernat-Wüsthoff (GBW) dipole satura-766 tion model [28], a modified GBW model which takes into account the effects of DGLAP evolution, termed the Bartels-768 Golec-Kowalski (BGK) dipole model [30] and the colour 769 glass condensate approach to the high parton density regime, named the Iancu-Itakura-Munier (IIM) dipole model [29].

GBW model: In the GBW model the dipole-proton cross section σ_{dip} is given by

$$\sigma_{\text{dip}}(x, r^2) = \sigma_0 \left(1 - \exp\left[-\frac{r^2}{4R_0^2(x)} \right] \right), \tag{25}$$

r where r corresponds to the transverse separation between (24) 772 the quark and the antiquark, and R_0^2 is an x-dependent scale parameter which represents the spacing of the gluons in the proton. R_0^2 takes the form, $R_0^2(x) = (x/x_0)^{\lambda} 1/\text{GeV}^2$, and is which corresponds to the size of a refitted equiprobable replica75 called the saturation radius. The cross-section normalisa-

784 DGLAP evolution.

BGK model with valence quarks: The dipole models are 825 The masses of the quarks are explicitly included as paramvalid in the low-x region only, where the valence quark con- 826 eters of the model. In addition to $\gamma^* g^* \to q\bar{q}$, the contributribution to the total proton momentum is 5% to 15% for x 827 tion from valence quarks is included via $\gamma^* q \to q$ by using a from 0.0001 to 0.01 [108]. The inclusive HERA measure- 828 CCFM evolution of valence quarks [129–131]. ments have a precision which is better than 2%. Therefore, HERAFitter provides the option of taking into account the 829 CCFM Grid Techniques: The CCFM evolution cannot be contribution of the valence quarks

IIM model: The IIM model assumes an expression for the IIM model: The IIM model assumes an expression for the given by the convolution method introduced in [131, dipole cross section which is based on the Balitsky-Kovchegov 132], the kernel $\tilde{\mathcal{A}}(x'', k_t, p)$ is determined from the MC soequation [109]. The explicit formula for σ_{dip} can be found in [29]. The alternative scale parameter \tilde{R} , x_0 and λ are fitted parameters of the model.

6.2 Transverse Momentum Dependent PDFs

QCD calculations of multiple-scale processes and complex final-states can necessitate the use of transverse-momentum dependent (TMD) [7], or unintegrated parton distribution and parton decay functions [110-118]. TMD factorisation has been proven recently [7] for inclusive DIS. TMD factorisation has also been proven in the high-energy (small-x) limit [119–121] for particular hadron-hadron scattering processes, like heavy flavour, vector boson and Higgs production.

In the framework of high-energy factorisation [119, 122, 123] the DIS cross section can be written as a convolution in both longitudinal and transverse momenta of the TMD parton distribution function $\mathcal{A}(x, k_t, \mu_F^2)$ with the off-shell parton scattering matrix elements as follows

$$\sigma_j(x,Q^2) = \int_x^1 dz \int d^2k_t \ \hat{\sigma}_j(x,Q^2,z,k_t) \ \mathscr{A}\left(z,k_t,\mu_F^2\right),$$
 (26)

where the DIS cross sections $\sigma_i(j=2,L)$ are related to the structure functions F_2 and F_L by $\sigma_i = 4\pi^2 F_i/Q^2$, and the hard-scattering kernels $\hat{\sigma}_i$ of Eq. 26 are k_t -dependent.

The factorisation formula in Eq. 26 allows resummation of logarithmically enhanced small-x contributions to all orders in perturbation theory, both in the hard scattering coef- 855 Functional Forms for TMD parametrisation: For the startthe dependence on the factorisation scale μ_F and on the fac- 857 form is used: torisation scheme [124, 125].

811

815

Phenomenological applications of this approach require matching of small-x contributions with finite-x contributions. To this end, the evolution of the transverse momentum de- where $\sigma^2 = Q_0^2/2$ and N, B, C, D, E are free parameters. Vapendent gluon density A is obtained by combining the re- 859 lence quarks are treated using the method of Ref. [129] as summation of small-x logarithmic corrections [126–128] with₈₆₀ described in Ref. [131] with a starting distribution taken medium-x and large-x contributions to parton splitting [11, 861 from any collinear PDF and imposition of the flavour sum 14, 15] according to the CCFM evolution equation [23–26]. 862 rule at every scale p.

scheme, using the boson-gluon fusion process ($\gamma^*g^* \to q\bar{q}$). 864 Fitter tools or with TMDplotter [35].

written easily in an analytic closed form. For this reason, a MC method is employed, which is, however, time-consuming and thus cannot be used directly in a fit program.

lution of the CCFM evolution equation, and then folded with a non-perturbative starting distribution $\mathcal{A}_0(x)$

$$x\mathscr{A}(x,k_t,p) = x \int dx' \int dx'' \mathscr{A}_0(x') \widetilde{\mathscr{A}}(x'',k_t,p) \, \delta(x'x''-x)$$
$$= \int dx' \mathscr{A}_0(x') \frac{x}{x'} \, \widetilde{\mathscr{A}}\left(\frac{x}{x'},k_t,p\right), \tag{27}$$

where k_t denotes the transverse momentum of the propagator gluon and p is the evolution variable.

The kernel $\tilde{\mathscr{A}}$ incorporates all of the dynamics of the evolution. It is defined on a grid of $50 \otimes 50 \otimes 50$ bins in x, k_t, p . The binning in the grid is logarithmic, except for the longitudinal variable x for which 40 bins in logarithmic spacing below 0.1, and 10 bins in linear spacing above 0.1

Calculation of the cross section according to Eq. 26 involves a time-consuming multidimensional MC integration, which suffers from numerical fluctuations. This cannot be 848 employed directly in a fit procedure. Instead the following 849 equation is applied:

$$\sigma(x,Q^2) = \int_x^1 dx_g \mathscr{A}(x_g, k_t, p) \hat{\sigma}(x, x_g, Q^2)$$
$$= \int_x^1 dx' \mathscr{A}_0(x') \tilde{\sigma}(x/x', Q^2), \tag{28}$$

where first $\tilde{\sigma}(x',Q^2)$ is calculated numerically with a MC integration on a grid in x for the values of Q^2 used in the 852 fit. Then the last step in Eq. 28 is performed with a fast numerical Gauss integration, which can be used directly in the

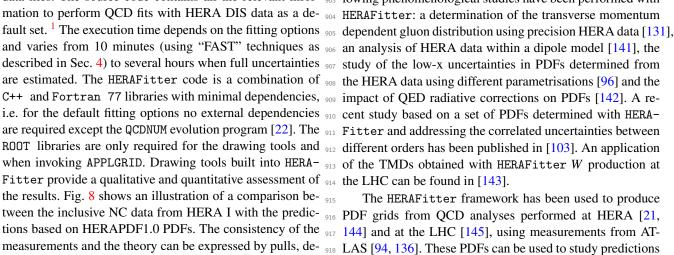

ficients and in the parton evolution, fully taking into account $_{856}$ ing distribution \mathcal{A}_0 , at the starting scale Q_0^2 , the following

$$x\mathcal{A}_0(x,k_t) = Nx^{-B}(1-x)^C \left(1 - Dx + E\sqrt{x}\right)$$
$$\times \exp[-k_t^2/\sigma^2], \tag{29}$$

The cross section σ_j , (j=2,L) is calculated in a FFN 863 The TMD parton densities can be plotted either with HERA-

7 HERAFitter Code Organisation

measurements and the theory can be expressed by pulls, de- 918 LAS [94, 136]. These PDFs can be used to study predictions fined as the difference between data and theory divided by 919 for SM or beyond SM processes. Furthermore, HERAFitter the uncorrelated error of the data. In each kinematic bin of 920 provides the possibility to perform various benchmarking the measurement, pulls are provided in units of standard de- 921 exercises [146] and impact studies for possible future col-922 liders as demonstrated by QCD studies at the LHeC [147].

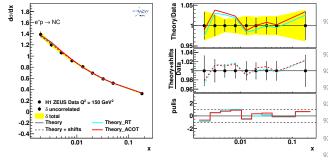

Fig. 8 An illustration of the consistency of HERA measurements [21] and the theory predictions, obtained in HERAFitter with the default drawing tool.

In HERAFitter there are also available cache options for 935 fast retrieval, fast evolution kernels, and the OpenMP (Open 936 Multi-Processing) interface which allows parallel applications of the GM-VFNS theory predictions in DIS.

8 Applications of HERAFitter

890

9 Summary

924 HERAFitter is the first open-source code designed for studies of the structure of the proton. It provides a unique and flexible framework with a wide variety of QCD tools to facilitate analyses of the experimental data and theoretical calculations.

The HERAFitter code, in version 1.1.0, has sufficient options to reproduce the different theoretical choices made 931 in MSTW, CTEQ and ABM fits. This will potentially make 932 it a valuable tool for benchmarking and understanding dif-933 ferences between PDF fits. Such a study would however need to consider a range of further questions, such as the choices of data sets, treatments of uncertainties, input parameter values, χ^2 definitions, etc.

The further progress of HERAFitter is driven by the latest QCD advances in theoretical calculations and in the precision of experimental data.

Acknowledgements HERAFitter developers team acknowledges the kind hospitality of DESY and funding by the Helmholtz Alliance "Physics The HERAFitter program has been used in a number of 942 at the Terascale" of the Helmholtz Association.
