1 Introduction

The recent discovery of the Higgs boson [2, 3] and the extensive searches for signals of new physics in LHC proton- 67 of fundamental parameters of QCD such as the heavy quark proton collisions demand high-precision calculations and com⁴⁸ masses and the strong coupling constant. It also provides a putations to test the validity of the Standard Model (SM) and 69 common platform for the comparison of different theoretical factorisation in Quantum Chromodynamics (QCD). Using 70 approaches. Furthermore, it can be used to test the impact of collinear factorisation, hadron inclusive cross sections may be written as

$$\sigma(\alpha_{s}(\mu_{R}^{2}), \mu_{R}^{2}, \mu_{F}^{2}) = \sum_{a,b} \int_{0}^{1} dx_{1} dx_{2} f_{a}(x_{1}, \mu_{F}^{2}) f_{b}(x_{2}, \mu_{F}^{2})$$

$$\times \hat{\sigma}^{ab}(x_{1}, x_{2}; \alpha_{s}(\mu_{R}^{2}), \mu_{R}^{2}, \mu_{F}^{2})$$

$$+ \mathcal{O}\left(\frac{\Lambda_{QCD}^{2}}{Q^{2}}\right)$$
(1)

where the cross section σ is expressed as a convolution of Parton Distribution Functions (PDFs) f_a and f_b with the parton cross section $\hat{\sigma}^{ab}$, involving a momentum transfer qsuch that $Q^2 = |q^2| \gg \Lambda_{QCD}^2$. At Leading-Order (LO), the PDFs represent the probability of finding a specific parton a (b) in the first (second) proton carrying a fraction x_1 (x_2) of its momentum. The indices a and b in Eq. 1 indicate the various kinds of partons, i.e. gluons, quarks and antiquarks of different flavours that are considered as the constituents of the proton. The PDFs depend on the factorisation scale, $\mu_{\rm F}$, while the parton cross sections depend on the strong coupling, α_s , and the factorisation and renormalisation scales, $\mu_{\rm F}$ and $\mu_{\rm R}$. The parton cross sections $\hat{\sigma}^{ab}$ are calculable in perturbative QCD (pQCD) whereas PDFs are non-perturbative and are usually constrained by global fits to a variety of experimental data. The assumption that PDFs can be found in Refs. [9, 10].

11 oretical predictions are brought together through numerous 54 the LHC and the Tevatron, respectively, provide compleof a tool to combine them together in a fast, efficient, opensource platform.

> This paper describes the open-source QCD fit platform 64 HERAFitter, which includes a set of tools to facilitate global QCD analyses of pp, $p\bar{p}$ and ep scattering data. It has been developed for the determination of PDFs and the extraction 71 new experimental data on the PDFs and on the SM parame-72 ters.

This paper is organised as follows: The general structure of HERAFitter is presented in section 2. In section 3 the various processes available in HERAFitter and the corre-₇₆ sponding theoretical calculations, performed within the framework of collinear factorisation and the DGLAP [11–15] formalism, are discussed. In section 4 tools for fast calculations of the theoretical predictions are presented. In section 5 the methodology to determine PDFs through fits based on various χ^2 definitions is explained. In particular, different treatments of correlated experimental uncertainties are presented. Alternative approaches to the DGLAP formalism are presented in section 6. The organisation of the HERAFitter 85 code is discussed in section 7, specific applications of the ₈₆ package are persented in section 8, which is followed by a 87 summary in section 9.

2 The HERAFitter Structure

89 The diagram in Fig. 1 gives a schematic overview of the $_{90}$ HERAFitter structure and functionality, which can be di-91 vided into four main blocks:

are universal, within a particular factorisation scheme [4–8], 92 Data: Measurements from various processes are implemented is crucial to this procedure. Table 1 The list of experimental data and theory calculations implemented in the HERAFitter package. The references for the individual calculations and schemes are given in the text.

However, the kinematic range of HERA data mostly covers low and medium ranges in x. Improvements in precision of PDFs require additional constraints on the gluon and quark distributions at high-x, better understanding of Fitter framework are listed in Tab. 1.

112 Theory: The PDFs are parametrised at a starting scale, Q_0^2 , by a chosen functional form with a set of free parameters p. These PDFs are evolved to the scale of the measurement Q^2 , $Q^2 > Q_0^2$. By default, the evolution uses the DGLAP 116 formalism [11-15] as implemented in QCDNUM [22]. Alternatively, the CCFM evolution [23-26] as implemented in uPDFevolv [27] can be chosen. The prediction of the cross section for a particular process is obtained, assuming factorisation, by the convolution of the evolved PDFs with the corresponding hard-process parton scattering cross section. Available theory calculations are listed in Tab. 1. Predictions using dipole models [28–30] can also be obtained.

224 QCD Analysis: The PDFs are determined in a least squares fit, minimising a χ^2 function that is constructed from the input data and theory predictions, with the MINUIT [31] program. In HERAFitter various choices are available for the treatment of experimental uncertainties. Correlated experimental uncertainties can be accounted for using a nuisance parameter method or a covariance matrix method as described in section 5.2. Different statistical assumptions for the distributions of the systematic uncertainties, e.g. Gaussian or LogNormal [32], can also be studied (see section 5.3).

Results: The resulting PDFs are provided in a format ready to be used by the LHAPDF library [33, 34] or by TMDlib [35]. HERAFitter drawing tools can be used to display the PDFs with their uncertainties at a chosen scale. As an example, the first set of PDFs extracted using HERAFitter from HERA I data, HERAPDF1.0 [21], is shown in Fig. 2 (taken from Ref. [21]). Note that following conventions, the PDFs are displayed as parton momentum distributions $xf(x, \mu_F^2)$.

3 Theoretical formalism using DGLAP evolution

In this section the theoretical formalism based on DGLAP [11–15] evolution is described.

A direct consequence of factorisation (Eq. 1) is that the scale dependence or "evolution" of the PDFs can be predicted by the renormalisation group equations. By requiring physical observables to be independent of $\mu_{\rm F}$, a representation of the parton evolution in terms of the DGLAP equa-150 tions is obtained:

$$\frac{d f_a(x, \mu_F^2)}{d \log \mu_F^2} = \sum_{b=q, \bar{q}, g} \int_x^1 \frac{dz}{z} P_{ab} \left(\frac{x}{z}; \mu_F^2\right) f_b(z, \mu_F^2), \qquad (2)$$

heavy quark distributions and decomposition of the light- 151 where the functions P_{ab} are the evolution kernels or splitting quark sea. For these purposes, measurements from fixed- 152 functions, which represent the probability of finding partarget experiments, the Tevatron and the LHC can be used. 153 ton a in parton b. They can be calculated as a perturbative The processes that are currently available within the HERA- 154 expansion in α_s . Once PDFs are determined at the initial scale $\mu_F^2 = Q_0^2$, their evolution to any other scale $Q^2 > Q_0^2$

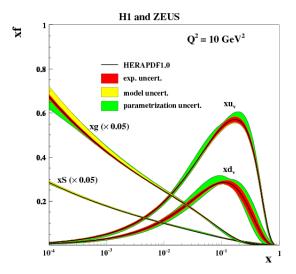

Fig. 2 Distributions of valence (xu_v, xd_v) , sea (xS) and the gluon (g)PDFs in HERAPDF1.0 [21]. The gluon and the sea distributions are scaled down by a factor of 20. The experimental, model and parametrisation uncertainties are shown as coloured bands.

is entirely determined by the DGLAP equations. The PDFs are then used to calculate cross sections for various different processes. Alternative approaches to DGLAP evolution, valid in different kinematic regimes, are also implemented in HERAFitter and will be discussed in section 6.

3.1 Deep Inelastic Scattering and Proton Structure

The formalism that relates the DIS measurements to pQCD and the PDFs has been described in detail in many extensive reviews (see e.g. Ref. [36]) and it is only briefly summarised here. DIS is the process where a lepton scatters off the partons in the proton by a virtual exchanged of a neutral (γ/Z) or charged (W^{\pm}) vector boson and, as a result, a scattered lepton and a multi-hadronic final state are produced. The 210 Zero-Mass Variable Flavour Number (ZM-VFN):

$$\frac{d^2 \sigma_{NC}^{e^{\pm} p}}{dx dQ^2} = \frac{2\pi \alpha^2 Y_+}{x Q^4} \sigma_{r,NC}^{e^{\pm} p},\tag{3}$$

$$\sigma_{r,NC}^{e^{\pm}p} = \tilde{F}_2^{\pm} \mp \frac{Y_-}{Y_+} x \tilde{F}_3^{\pm} - \frac{y^2}{Y_+} \tilde{F}_L^{\pm}, \tag{4}$$

pling constant. The generalised structure functions $\tilde{F}_{2,3}$ can 225 batively in the final state. The lowest order process is the

180 be written as linear combinations of the proton structure functions F_2^{γ} , $F_{2,3}^{\gamma Z}$ and $F_{2,3}^{Z}$, which are associated with pure photon exchange terms, photon-Z interference terms and pure Z exchange terms, respectively. The structure function \tilde{F}_2 is the dominant contribution to the cross section, $x\tilde{F}_3$ becomes important at high Q^2 and \tilde{F}_L is sizable only at high y. In the framework of pQCD the structure functions are directly related to the PDFs, i.e. at leading order (LO) F_2 is the weighted momentum sum of quark and anti-quark distributions, xF_3 is related to their difference, and F_L vanishes. At higher orders, terms related to the gluon distribution appear, in particular F_L is strongly related to the low-x gluon. The inclusive CC ep cross section, analogous to the NC ep

case, can be expressed in terms of another set of structure 194 functions, \tilde{W} :

$$\frac{d^2 \sigma_{CC}^{e^{\pm} p}}{dx dQ^2} = \frac{1 \pm P}{2} \frac{G_F^2}{2\pi x} \left[\frac{m_W^2}{m_W^2 + Q^2} \right] \sigma_{r,CC}^{e^{\pm} p}$$
 (5)

$$\sigma_{r,CC}^{e^{\pm}p} = Y_{+}\tilde{W}_{2}^{\pm} \mp Y_{-}x\tilde{W}_{3}^{\pm} - y^{2}\tilde{W}_{L}^{\pm},\tag{6}$$

where P represents the lepton beam polarisation. At LO in α_s , the CC e^+p and e^-p cross sections are sensitive to different combinations of the quark flavour densities.

Beyond LO, the QCD predictions for the DIS structure functions are obtained by convoluting the PDFs with appropriate hard-process scattering matrix elements, which are referred to as coefficient functions.

The DIS measurements span a large range of Q^2 from a few GeV² to about 10⁵ GeV², crossing heavy quark mass thresholds, thus the treatment of heavy quark (charm and beauty) production and the chosen values of their masses become important. There are different schemes for the treatment of heavy quark production. Several variants of these schemes are implemented in HERAFitter and they are briefly 209 discussed below.

common DIS kinematic variables are the scale of the pro- 211 In this scheme [37], the heavy quarks appear as partons in cess Q^2 , which is the absolute squared four-momentum of 212 the proton at Q^2 values above $\sim m_h^2$ (heavy quark mass) and the exchange boson, Bjorken x, which can be related in the 213 they are then treated as massless in both the initial and fiparton model to the momentum fraction that is carried by 214 nal states of the hard scattering process. The lowest order the struck quark, and the inelasticity y. These are related by 215 process is the scattering of the lepton off the heavy quark $y = Q^2/sx$, where s is the squared centre-of-mass (c.o.m.) 216 via electroweak boson exchange. This scheme is expected to be reliable in the region where $Q^2 \gg m_h^2$. In HERAFitter The NC cross section can be expressed in terms of gener- 218 this scheme is available for the DIS structure function cal-219 culation via the interface to the QCDNUM [22] package, thus it benefits from the fast QCDNUM convolution engine.

221 Fixed Flavour Number (FFN):

(4) 222 In this rigorous quantum field theory scheme [38–40], only 223 the gluon and the light quarks are considered as partons where $Y_{\pm}=1\pm(1-y)^2$ and α is the electromagnetic cou- 224 within the proton and massive quarks are produced perturbation. heavy quark-antiquark pair production via boson-gluon fu- 277 sion. In HERAFitter this scheme can be accessed via the 278 QCDNUM implementation or through the interface to the opensource code OPENQCDRAD [41] as implemented by the ABM group. This scheme is reliable for $Q^2 \sim m_h^2$. In QCDNUM, the calculation of the heavy quark contributions to DIS structure functions are available at Next-to-Leading Order (NLO) and only electromagnetic exchange contributions are taken into account. In the OPENQCDRAD implementation the heavy quark contributions to CC structure functions are also available and, for the NC case, the QCD corrections to the coefficient functions in Next-to-Next-to Leading Order (NNLO) are provided in the best currently known approximation [42]. The OPENQCDRAD implementation uses in addition the running heavy quark mass in the \overline{MS} scheme [43].

It is sometimes argued that this scheme reduces the sensitivity of the DIS cross sections to higher order corrections [42]. It is also known to have smaller non-perturbative corrections than the pole mass scheme [44].

General-Mass Variable Flavour Number (GM-VFN):

In this scheme [45], heavy quark production is treated for $Q^2 \sim m_h^2$ in the FFN scheme and for $Q^2 \gg m_h^2$ in the massless scheme with a suitable interpolation in between. The details of this interpolation differ between implementations. The PDF groups that use GM-VFN schemes are MSTW, CT (CTEQ), NNPDF, and HERAPDF. HERAFitter implements different variants of the GM-VFN scheme.

GM-VFN Thorne-Roberts scheme: The Thorne-Roberts (TR) scheme [46] was designed to provide a smooth transition from the massive FFN scheme at low scales $Q^2 \gg m_h^2$. Because the original version was technically difficult to implement beyond NLO, it was updated to the TR' scheme [47]. There are two variants of the TR' schemes: TR' standard (as used in MSTW PDF sets [16, 47]) and TR' optimal [48], with a smoother transition across the heavy quark threshold region. Both TR' variants are accessible within the HERAFitter package at LO, NLO and NNLO.

GM-VFN ACOT scheme: The Aivazis-Collins-Olness- 289 3.3 Diffractive PDFs Tung (ACOT) scheme belongs to the group of VFN fac-

and ACOT-Full schemes is illustrated in Fig. 3 (taken from [21]).

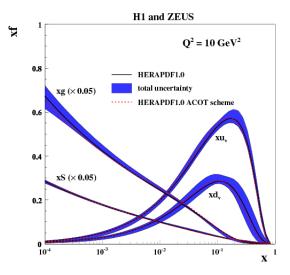

Fig. 3 Distributions of valence (xu_v, xd_v) , sea (xS) and the gluon (g)PDFs in HERAPDF1.0 [21] with their total uncertainties at the scale of $Q^2 = 10 \text{ GeV}^2$ obtained using the TR' scheme and compared to the PDFs obtained with the ACOT-Full scheme using the k-factor technique (red). The gluon and the sea distributions are scaled down by a factor of 20.

279 3.2 Electroweak Corrections to DIS

280 Calculations of higher-order electroweak corrections to DIS 281 at HERA are available in HERAFitter in the on-shell scheme. $Q^2 \sim m_h^2$ to the massless ZM-VFNS scheme at high scales $\frac{201}{282}$ In this scheme, the masses of the gauge bosons m_W and m_Z are treated as basic parameters together with the top, ²⁸⁴ Higgs and fermion masses. These electroweak corrections are based on the EPRC package [53]. The code calculates the running of the electromagnetic coupling α using the most recent parametrisation of the hadronic contribution [54] as well as an older version from Burkhard [55].

torisation schemes that use the renormalisation method 290 About 10% of deep inelastic interactions at HERA are diffracof Collins-Wilczek-Zee (CWZ) [49]. This scheme uni- 291 tive, such that the interacting proton stays intact ($ep \rightarrow eXp$). fies the low scale $Q^2 \sim m_h^2$ and high scale $Q^2 > m_h^2$ re- 292 The proton is well separated from the rest of the hadronic figions in a coherent framework across the full energy 293 nal state by a large rapidity gap. This is interpreted as the range. Within the ACOT package, the following variants $_{294}$ dissociation of the virtual photon into a hadronic system X of the ACOT scheme are available: ACOT-Full [50], S- 295 with a squared invariant mass much smaller than the photon-ACOT- χ [51, 52], ACOT-ZM [50], $\overline{\text{MS}}$ at LO and NLO. 296 proton c.o.m. energy $W^2 = ys - Q^2 + m_p^2(1-y)$, where m_p For the longitudinal structure function higher order cal- 297 is the proton mass. Such a process is often assumed to be culations are also available. A comparison of PDFs ex- 298 mediated by the exchange of a hard Pomeron or a secondary tracted from QCD fits to the HERA data with the TR' 299 Reggeon with vacuum quantum numbers. This factorisable

Pomeron picture has proved remarkably successful in the $326 \cos \theta$ in the parton c.o.m. frame can be written as [60, 61]: description of most of the diffractive data. Diffractive parton distributions (DPDFs) can be determined from QCD fits to diffractive cross sections in a similar way to the determination of the standard PDFs [56].

In addition to the usual DIS variables x, Q^2 , extra kinematic variables are needed to describe the diffractive process. These are the squared four-momentum transfer of the exchanged Pomeron or Reggeon, t, and the mass m_X of the diffractively produced final state. In practice, the variable m_X is often replaced by the dimensionless quantity $\beta = \frac{Q^2}{m_X^2 + Q^2 \sin^2}$. The corresponding triple differential CC cross section has In models based on a factorisable Pomeron, β may be viewed 333 the form: at LO as the fraction of the Pomeron longitudinal momentum, x_{IP} , which is carried by the struck parton, $x = \beta x_{IP}$, where *P* denotes the momentum of the proton.

For the inclusive case, the diffractive cross-section reads as:

$$\frac{d^4\sigma}{d\beta\,dQ^2dx_{IP}dt} = \frac{2\pi\alpha^2}{\beta\,Q^4}\,\left(1 + (1-y)^2\right)\overline{\sigma}^{D(4)}(\beta,Q^2,x_{IP},t) \tag{7}$$

with the "reduced cross-section":

$$\overline{\sigma}^{D(4)} = F_2^{D(4)} - \frac{y^2}{1 + (1 - y)^2} F_L^{D(4)}.$$
 (8)

convolutions of calculable coefficient functions with the diffraçe matic cuts. tive quark and gluon distribution functions, which in general 343 depend on x_{IP} , Q^2 , β and t.

The diffractive PDFs [57, 58] in HERAFitter are implemented as a sum of two factorised contributions:

$$\Phi_{IP}(x_{IP},t) f_a^{IP}(\beta,Q^2) + \Phi_{IR}(x_{IP},t) f_a^{IR}(\beta,Q^2),$$
 (9)

where $\Phi(x_{IP},t)$ are the Reggeon and Pomeron fluxes. The Reggeon PDFs, f_a^{IR} are fixed as those of the pion, while the Pomeron PDFs, f_a^{IP} , can be obtained from a fit to the data.

3.4 Drell-Yan Processes in pp or $p\bar{p}$ Collisions

The Drell-Yan (DY) process provides valuable information about PDFs. In pp and $p\bar{p}$ scattering, the Z/γ^* and W pro- $_{356}$ 3.5 Jet Production in ep and pp or $p\bar{p}$ Collisions duction probe bi-linear combinations of quarks. Completially sensitive to the gluon distribution [59].

variant mass m, boson rapidity y and lepton scattering angle 366 of jet production. Similarly to the DY case, the calculation

$$\frac{d^3\sigma}{dmdyd\cos\theta} = \frac{\pi\alpha^2}{3ms} \sum_{q} \hat{\sigma}^q(\cos\theta, m)
\times \left[f_q(x_1, m^2) f_{\bar{q}}(x_2, m^2) + (q \leftrightarrow \bar{q}) \right], \quad (10)$$

where s is the squared c.o.m. beam energy, the parton momentum fractions are given by $x_{1,2} = \frac{m}{\sqrt{s}} \exp(\pm y), f_q(x_1, m^2)$ are the PDFs at the scale of the invariant mass, and $\hat{\sigma}^q$ is the parton-parton hard scattering cross section.

$$\frac{d^3\sigma}{dmdyd\cos\theta} = \frac{\pi\alpha^2}{48s\sin^4\theta_W} \frac{m^3(1-\cos\theta)^2}{(m^2-m_W^2) + \Gamma_W^2 m_W^2} \times \sum_{q_1,q_2} V_{q_1q_2}^2 f_{q_1}(x_1,m^2) f_{q_2}(x_2,m^2), \tag{11}$$

 $_{\mbox{\scriptsize 334}}$ where $V_{q_1q_2}$ is the Cabibbo-Kobayashi-Maskawa (CKM) quark (7) $_{335}$ mixing matrix and m_W and Γ_W are the W boson mass and de-336 cay width, respectively.

The simple LO form of these expressions allows for the analytic calculations of integrated cross sections. In both NC and CC expressions the PDFs depend only on the boson rapidity y and invariant mass m, while the integral in $\cos \theta$ can The diffractive structure functions can be expressed as 341 be evaluated analytically even for the case of realistic kine-

> Beyond LO, the calculations are often time-consuming and Monte Carlo generators are often employed. Currently, the predictions for W and Z/γ^* production are available up 346 to NNLO and the predictions for W, Z in association with heavy flavour quarks is available to NLO.

There are several possibilities to obtain the theoretical predictions for DY production in HERAFitter. The NLO and NNLO calculations are time consuming and k-factor or fast grid techniques must be employed (see section 4 for details), which are interfaced to programs such as MCFM [62-₃₅₃ 64], available for NLO calculations, or FEWZ [65] and DYNNLO [66] 354 for NLO and NNLO, with electro-weak corrections estimated 355 using MCSANC [67, 68].

mentary information on the different quark densities can be $_{357}$ The cross section for production of high p_T hadronic jets obtained from the W^{\pm} asymmetry (d, u and their ratio), the 358 is sensitive to the high-x gluon PDF (see e.g. Ref. [16]). ratio of the W and Z cross sections (sensitive to the flavour 359 Therefore this process can be used to improve the determicomposition of the quark sea, in particular to the s-quark 360 nation of the gluon PDF, which is particularly important for distribution), and associated W and Z production with heavy 361 Higgs production and searches for new physics. 3.6 Top-quark Production in pp or $p\bar{p}$ Collisions

At the LHC, top-quark pairs $(t\bar{t})$ are produced dominantly via gg fusion. Thus, LHC measurements of the $t\bar{t}$ cross section provide additional constraints on the gluon distribution at medium to high values of x, on α_s and on the top-quark mass, m_t [74]. Precise predictions for the total $t\bar{t}$ cross section are available to NNLO [75]. They can be computed Differential $t\bar{t}$ cross section predictions at NLO can be obtained using MCFM [64, 77-80] interfaced to HERAFitter with fast grid techniques.

Single top quarks are produced via electroweak interactions and the measurement of their production cross section default. However, for the ACOT scheme, due to exceptioncan be used, for example, to probe the ratio of the u and ddensities in the proton as well as the b-quark PDF. Predictions for single-top production are available to NLO accuracy using MCFM.

4 Computational Techniques

tions in order to maximise their impact in PDF fits. Perturbaat higher orders due to the increasing number of relevant demanding higher-order calculations into iterative fits is thus not possible currently. However, a full repetition of the pernique. Both are available in HERAFitter.

4.1 k-factor Technique

367 is very demanding in terms of computing power. Therefore 412 steps the theory prediction is derived from the fast lower-

This procedure, however, neglects the fact that the kfactors are PDF dependent, and as a consequence, they have 416 to be re-evaluated for the newly determined PDF at the end of the fit for a consistency check. The fit must be repeated until input and output k-factors have converged. In summary, this technique avoids iteration of the higher-order cal-420 culation at each step, but still requires typically a few re-421 evaluations.

In HERAFitter, the k-factor technique is also used for 423 the fast computation of the time-consuming GM-VFN schemes for heavy quarks in DIS. "FAST" heavy-flavour schemes are implemented with k-factors defined as the ratio of calculawithin HERAFitter via an interface to the program HATHOR [76] tions at the same perturbative order but for massive vs. massless quarks, e.g. NLO (massive)/NLO (massless). These k-428 factors are calculated only for the starting PDF and hence, 429 the "FAST" heavy flavour schemes should only be used for 430 quick checks. Full heavy flavour schemes should be used by $_{432}$ ally long computation times, the k-factors are used in the 433 default setup of HERAFitter.

4.4 4.2 Fast Grid Techniques

435 Fast grid techniques exploit the fact that iterative PDF fit-436 ting procedures do not impose completely arbitrary changes 437 to the types and shapes of the parameterised functions that Precise measurements require accurate theoretical predic- 438 represent each PDF. Instead, it can be assumed that a generic ⁴³⁹ PDF can be approximated by a set of interpolating functive calculations become more complex and time-consuming 440 tions with a sufficient number of judiciously chosen sup-441 port points. The accuracy of this approximation is checked Feynman diagrams. The direct inclusion of computationally 442 and optimised such that the approximation bias is negligibly small compared to the experimental and theoretical accu-444 racy. This method can be used to perform the time consumturbative calculation for small changes in input parameters 445 ing higher-order calculations (Eq. 1) only once for the set of is not necessary at each step of the iteration. Two methods 446 interpolating functions. Further iterations of the calculation have been developed which take advantage of this to solve 447 for a particular PDF set are fast, involving only sums over the problem: the k-factor technique and the fast grid tech- 448 the set of interpolators multiplied by factors depending on the PDF. This approach can be used to calculate the cross sections of processes involving one or two hadrons in the initial state and to assess their renormalisation and factorisation scale variation.

This technique was pioneered by the fastNLO project [81] The k-factors are defined as the ratio of the prediction of a 454 to facilitate the inclusion of time consuming NLO jet cross higher-order (slow) pQCD calculation to a lower-order (fast) 455 section predictions into PDF fits. The APPLGRID [82] project calculation using the same PDF. Because the k-factors de-456 developed an alternative method and, in addition to jets, expend on the phase space probed by the measurement, they 457 tended its applicability to other scattering processes, such have to be stored including their dependence on the relevant 458 as DY and heavy quark pair production in association with kinematic variables. Before the start of a fitting procedure, a 459 boson production. The packages differ in their interpolation table of k-factors is computed once for a fixed PDF with the 460 and optimisation strategies, but both of them construct tatime consuming higher-order code. In subsequent iteration 461 bles with grids for each bin of an observable in two steps:

514

in the first step, the accessible phase space in the parton momentum fractions x and the renormalisation and factorisation scales μ_R and μ_F is explored in order to optimise the table size. In the second step the grid is filled for the requested observables. Higher-order cross sections can then be obtained very efficiently from the pre-produced grids while varying externally provided PDF sets, μ_R and μ_F , or the strong coupling $\alpha_s(\mu_R)$. This approach can in principle be extended to arbitrary processes. This requires an interface between the higher-order theory programs and the fast interpolation frameworks. Currently available processes for each package are as follows:

- The fastNLO project [81] has been interfaced to the NLOJet++ program [72] for the calculation of jet production in DIS [83] as well as 2- and 3-jet production in hadron-hadron collisions at NLO [73, 84]. Threshold corrections at 2-loop order, which approximate the NNLO for the inclusive jet cross section, have also been included into the framework [85] following Ref. [86]. The latest version of the fastNLO convolution program [87] allows for the creation of tables in which renormalisation and factorisation scales can be varied as a function of two pre-defined observables, e.g. jet transverse momentum p_{\perp} and Q for DIS. Recently, the differential calculation of top-pair production in hadron collisions at approximate NNLO [88] has been interfaced to fastNLO. The fastNLO code is available online [89]. Jet cross-section grids computed for the kinematics of various experiments can be downloaded from this site. Dedicated fastNLO libraries and tables with theory presurements are included into the HERAFitter package. For the HERAFitter implementation, the evaluation of the strong coupling constant is done consistently with the PDF evolution from the QCDNUM code.
- In the APPLGRID package [82, 90], in addition to jet cross sections for $pp(p\bar{p})$ and DIS processes, calculations of DY production are also implemented. The grids are generated with the customised versions of the MCFM parton level DY generator [62–64]. Variation of the renormalisation and factorisation scales is possible a posteriori, when calculating theory predictions with the APPL-GRID tables, and independent variation of α_S is also allowed. For higher-order predictions, the k-factors technique can also be applied within the APPLGRID framework.

As an example, the HERAFitter interface to APPLGRID was used by the ATLAS [91] and CMS [92] collaboraton. The ATLAS strange PDF extracted employing these 537 tional forms and flavour decompositions: techniques is displayed in Fig. 4 together with a comparison to the global PDF sets CT10 [17] and NNPDF2.1 [18] (taken from [91]).

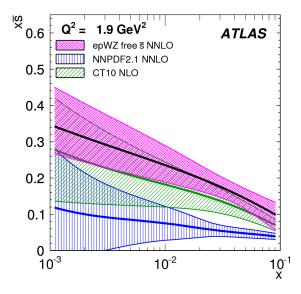

Fig. 4 The strange antiquark distribution versus x for the ATLAS epWZ free \$\bar{s}\$ NNLO fit [91] (magenta band) compared to predictions from NNPDF2.1 (blue hatched) and CT10 (green hatched) at $Q^2 = 1.9 \text{ GeV}^2$. The ATLAS fit was performed using a k-factor approach for NNLO corrections.

515 5 Fit Methodology

When performing a QCD analysis to determine PDFs there are various assumptions and choices to be made concerning, 518 for example, the functional form of the input parametrisa-519 tion, the treatment of heavy quarks and their mass values, al-520 ternative theoretical calculations, alternative representations dictions for comparison to particular cross section mea- $_{521}$ of the fit χ^2 and for different ways of treating correlated sys-522 tematic uncertainties. It is useful to discriminate or quantify 523 the effect of a chosen ansatz within a common framework and HERAFitter is optimally designed for such tests. The methodology employed by HERAFitter relies on a flexible and modular framework that allows for independent integra-527 tion of state-of-the-art techniques, either related to the inclusion of a new theoretical calculation, or of new approaches to treat data and their uncertainties.

> In this section we describe the available options for the 531 fit methodology in HERAFitter. In addition, as an alterna-532 tive approach to a complete QCD fit, the Bayesian reweighting method, which is also available in HERAFitter, is de-534 scribed.

535 5.1 Functional Forms for PDF Parametrisation

tions to extract the strange quark distribution of the pro- 536 The PDFs can be parametrised using several predefined func-

Standard Polynomials: The standard polynomial form is the most commonly used. A polynomial functional form is used

to parametrise the *x*-dependence of the PDFs, where index *j* denotes each parametrised PDF flavour:

$$xf_i(x) = A_i x^{B_j} (1-x)^{C_j} P_i(x).$$
 (12)

The parametrised PDFs are the valence distributions xu_v and xd_v , the gluon distribution xg, and the u-type and d-type sea, $x\bar{U}$, $x\bar{D}$, where $x\bar{U}=x\bar{u}$, $x\bar{D}=x\bar{d}+x\bar{s}$ at the starting scale, which is chosen below the charm mass threshold. The form of polynomials $P_j(x)$ can be varied. The form $(1+\varepsilon_j\sqrt{x}+D_jx+E_jx^2)$ is used for the HERAPDF [21] with additional constraints relating to the flavour decomposition of the light sea. This parametrisation is termed HERAPDF-style. The polynomial can also be parametrised in the CTEQ-style, where $P_j(x)$ takes the form $e^{a_3x}(1+e^{a_4}x+e^{a_5}x^2)$ and, in contrast to the HERAPDF-style, this is positive by construction. QCD number and momentum sum rules are used to determine the normalisations A for the valence and gluon distributions, and the sum-rule integrals are solved analytically.

Bi-Log-Normal Distributions: This parametrisation is motivated by multi-particle statistics and has the following functional form:

$$xf_j(x) = a_j x^{p_j - b_j \log(x)} (1 - x)^{q_j - d_j \log(1 - x)}.$$
 (13)

This function can be regarded as a generalisation of the standard polynomial form described above, however, numerical integration of Eq. 13 is required in order to impose the QCD sum rules.

Chebyshev Polynomials: A flexible parametrisation based on the Chebyshev polynomials can be employed for the gluon and sea distributions. Polynomials with argument $\log(x)$ are considered for better modelling the low-x asymptotic behaviour of those PDFs. The polynomials are multiplied by a factor of (1-x) to ensure that they vanish as $x \to 1$. The resulting parametric form reads

$$xg(x) = A_g (1-x) \sum_{i=0}^{N_g-1} A_{g_i} T_i \left(-\frac{2\log x - \log x_{\min}}{\log x_{\min}} \right), \quad (14)$$

$$xS(x) = (1 - x) \sum_{i=0}^{N_S - 1} A_{S_i} T_i \left(-\frac{2 \log x - \log x_{\min}}{\log x_{\min}} \right), \qquad (15)$$

where T_i are first-type Chebyshev polynomials of order i. The normalisation factor A_g is derived from the momentum sum rule analytically. Values of $N_{g,S}$ to 15 are allowed, however the fit quality is already similar to that of the standard-polynomial parametrisation from $N_{g,S} \geq 5$ and has a similar number of free parameters. Fig. 5 (taken from [93]) shows a comparison of the gluon distribution obtained with the parametrisation Eqs. 14, 15 to the standard-polynomial one, for $N_{g,S} = 9$.

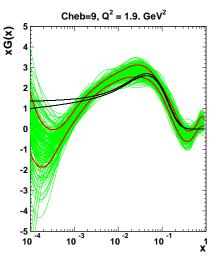

Fig. 5 The gluon density is shown at the starting scale $Q^2 = 1.9 \, \text{GeV}^2$. The black lines correspond to the uncertainty band of the gluon distribution using a standard parametrisation and it is compared to the case of the Chebyshev parametrisation [93]. The uncertainty band for the latter case is estimated using the Monte Carlo technique (see section 5.3) with the green lines denoting fits to data replica. Red lines indicate the standard deviation about the mean value of these replicas.

External PDFs: HERAFitter also provides the possibility to access external PDF sets, which can be used to compute theoretical predictions for the cross sections for all the processes available in HERAFitter. This is possible via an interface to LHAPDF [33, 34] providing access to the global PDF sets. HERAFitter also allows one to evolve PDFs from LHAPDF using QCDNUM. Fig. 6 illustrates a comparison of various gluon PDFs accessed from LHAPDF as produced with the drawing tools available in HERAFitter.

5.2 Representation of χ^2

The PDF parameters are determined in HERAFitter by minimisation of a χ^2 function taking into account correlated and uncorrelated measurement uncertainties. There are vari- 622 as additive or multiplicative, as described above. The statisous forms of χ^2 , e.g. using a covariance matrix or providing 623 related systematic uncertainty for each measured data point. 625 parameters is performed analytically, however, for more de-The options available in HERAFitter are the following:

Covariance Matrix Representation: For a data point μ_i with a corresponding theory prediction m_i , the χ^2 function can be expressed in the following form:

$$\chi^{2}(m) = \sum_{i,k} (m_{i} - \mu_{i}) C_{ik}^{-1}(m_{k} - \mu_{k}), \tag{16}$$

where the experimental uncertainties are given as a covariance matrix C_{ik} for measurements in bins i and k. The ⁶³¹ covariance matrix C_{ik} is given by a sum of statistical, uncorrelated and correlated systematic contributions:

$$C_{ik} = C_{ik}^{stat} + C_{ik}^{uncor} + C_{ik}^{sys}. (17)$$

Using this representation one cannot distinguish the effect of each source of systematic uncertainty.

Nuisance Parameter Representation: In this case, the χ^2 is expressed as

$$\chi^{2}(m,b) = \sum_{i} \frac{\left[\mu_{i} - m_{i} \left(1 - \sum_{j} \gamma_{j}^{i} b_{j}\right)\right]^{2}}{\delta_{i,\text{unc}}^{2} m_{i}^{2} + \delta_{i,\text{stat}}^{2} \mu_{i} m_{i} \left(1 - \sum_{j} \gamma_{j}^{i} b_{j}\right)} + \sum_{j} b_{j}^{2}, \frac{642}{643}$$
(18) 644

where, $\delta_{i,\text{stat}}$ and $\delta_{i,\text{unc}}$ are relative statistical and uncorrelated systematic uncertainties of the measurement i. 647 Further, γ_i^i quantifies the sensitivity of the measurement ₆₄₈ to the correlated systematic source j. The function χ^2 649 depends on the set of systematic nuisance parameters b_i . 650 This definition of the χ^2 function assumes that system- 651 atic uncertainties are proportional to the central predic- 652 tion values (multiplicative uncertainties, $m_i(1-\sum_i \gamma_i^i b_i)$), 653 whereas the statistical uncertainties scale with the square 654 root of the expected number of events. However, addi- 655 tive treatment of uncertainties is also possible in HERA- 656

During the χ^2 minimisation, the nuisance parameters b_i 658 and the PDFs are determined, such that the effect of dif- 659 ferent sources of systematic uncertainties can be distin- 660

Mixed Form Representation: In some cases, the statisti- 662 cal and systematic uncertainties of experimental data are 663 provided in different forms. For example, the correlated 664

experimental systematic uncertainties are available as nuisance parameters, but the bin-to-bin statistical correlations are given in the form of a covariance matrix. HERA-Fitter offers the possibility to include such mixed forms of information.

621 Any source of measured systematic uncertainty can be treated tical uncertainties can be included as additive or following nuisance parameters to encode the dependence of each cor- 624 the Poisson statistics. Minimisation with respect to nuisance tailed studies of correlations individual nuisance parameters can be included into the MINUIT minimisation.

5.3 Treatment of the Experimental Uncertainties

616

617

619

Three distinct methods for propagating experimental uncertainties to PDFs are implemented in HERAFitter and reviewed here: the Hessian, Offset, and Monte Carlo method.

Hessian (Eigenvector) method: The PDF uncertainties reflecting the data experimental uncertainties are estimated by examining the shape of the χ^2 function in the neighbourhood of the minimum [94]. Following the approach of Ref. [94], the Hessian matrix is defined by the second derivatives of χ^2 on the fitted PDF parameters. The matrix is diagonalised and the Hessian eigenvectors are computed. Due to orthogonality these vectors correspond to independent sources of uncertainty in the obtained

Offset method: The Offset method [95] uses the χ^2 function for the central fit, but only uncorrelated uncertainties are taken into account. The goodness of the fit can no longer be judged from the χ^2 since correlated uncertainties are ignored. The correlated uncertainties are propagated into the PDF uncertainties by performing variants of the fit with the experimental data varied by $\pm 1\sigma$ from the central value for each systematic source. The resulting deviations of the PDF parameters from the ones obtained in the central fit are statistically independent, and they can be combined in quadrature to derive a total PDF systematic uncertainty.

The uncertainties estimated by the offset method are generally larger than those from the Hessian method.

Monte Carlo method: The Monte Carlo (MC) technique [96, 97] can also be used to determine PDF uncertainties. The uncertainties are estimated using pseudo-data replicas (typically > 100) randomly generated from the measurement central values and their systematic and statistical uncertainties taking into account all point-to-point correlations. The QCD fit is performed for each replica and the PDF central values and their experimental uncertainties are estimated from the distribution of the PDF parameters obtained in these fits, by taking the mean values and standard deviations over the replicas.

674

675

676

677

678

680

681

682

683

The MC method has been checked against the standard error estimation of the PDF uncertainties obtained by the Hessian method. A good agreement was found between the methods provided that Gaussian distributions of statistical and systematic uncertainties are assumed in the MC approach [32]. A comparison is illustrated in Fig. 7. Similar findings were reported by the MSTW global analysis [98].

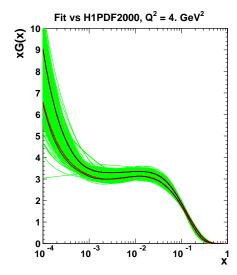

Fig. 7 Comparison between the standard error calculations as employed by the Hessian approach (black lines) and the MC approach 701 data on PDFs. Bayesian Reweighting was first proposed for (with more than 100 replicas) assuming Gaussian distribution for uncertainty distributions, shown here for each replica (green lines) together with the evaluated standard deviation (red lines) [32]. The black and red lines in the figure are superimposed because agreement of the $\,^{704}$ methods is so good that it is hard to distinguish them.

Since the MC method requires large number of replicas, 708 the eigenvector representation is a more convenient way 709 MC to eigenvector representation as shown by [99]. Tools $_{711}$ mented in HERAFitter. to perform this transformation are provided with HERA-Fitter and were recently employed for the representation of correlated sets of PDFs at different perturbative orders [100].

The nuisance parameter representation of χ^2 in Eq. 18 is derived assuming symmetric experimental errors, however, the published systematic uncertainties are often asymmetric. HERAFitter provides the possibility to use asymmetric systematic uncertainties. The implementation relies on the assumption that asymmetric uncertainties can be described

modified as follows

$$\gamma_j^i \to \omega_j^i b_j + \gamma_j^i,$$
 (19)

where the coefficients ω_i^i , γ_i^i are defined from the maximum and minimum shifts of the cross sections due to a variation of the systematic uncertainty j, S_{ij}^{\pm} ,

$$\omega_{j}^{i} = \frac{1}{2} \left(S_{ij}^{+} + S_{ij}^{-} \right), \qquad \gamma_{j}^{j} = \frac{1}{2} \left(S_{ij}^{+} - S_{ij}^{-} \right).$$
 (20)

5.4 Treatment of the Theoretical Input Parameters

The results of a QCD fit depend not only on the input data but also on the input parameters used in the theoretical calculations. Nowadays, PDF groups address the impact of the choices of theoretical parameters by providing alternative 690 PDFs with different choices of the mass of the charm quarks, m_c , mass of the bottom quarks, m_b , and the value of $\alpha_s(m_Z)$. Other important aspects are the choice of the functional form for the PDFs at the starting scale and the value of the starting scale itself. HERAFitter provides the possibility of different user choices of all these inputs.

5.5 Bayesian Reweighting Techniques

697 As an alternative to performing a full QCD fit, HERAFitter allows the user to assess the impact of including new data in an existing fit using the Bayesian Reweighting technique. The method provides a fast estimate of the impact of new PDF sets delivered in the form of MC replicas by [96] and further developed by the NNPDF Collaboration [101, 102]. More recently, a method to perform Bayesian Reweighting 705 studies starting from PDF fits for which uncertainties are 706 provided in the eigenvector representation has been also developed [98]. The latter is based on generating replica sets by introducing Gaussian fluctuations on the central PDF set with a variance determined by the PDF uncertainty given to store the PDF uncertainties. It is possible to transform ₇₁₀ by the eigenvectors. Both reweighting methods are imple-

> The Bayesian Reweighting technique relies on the fact that MC replicas of a PDF set give a representation of the probability distribution in the space of PDFs. In particular, the PDFs are represented as ensembles of N_{rep} equiprobable (i.e. having weights equal to unity) replicas, $\{f\}$. The central value for a given observable, $\mathcal{O}(\{f\})$, is computed as the average of the predictions obtained from the ensemble as

$$\langle \mathcal{O}(\{f\}) \rangle = \frac{1}{N_{\text{rep}}} \sum_{k=1}^{N_{\text{rep}}} \mathcal{O}(f^k),$$
 (21)

by a parabolic function. The nuisance parameter in Eq. 18 is 712 and the uncertainty as the standard deviation of the sample.

Upon inclusion of new data the prior probability distri- 734 6.1 Dipole Models bution, given by theoriginal PDF set, is modified according is updated according to

$$w_k = \frac{(\chi_k^2)^{\frac{1}{2}(N_{\text{data}} - 1)} e^{-\frac{1}{2}\chi_k^2}}{\frac{1}{N_{\text{rep}}} \sum_{k=1}^{N_{\text{rep}}} (\chi_k^2)^{\frac{1}{2}(N_{\text{data}} - 1)} e^{-\frac{1}{2}\chi_k^2}},$$
(22)

where $N_{\rm data}$ is the number of new data points, k denotes the specific replica for which the weight is calculated and χ_k^2 is the χ^2 of the new data obtained using the k-th PDF replica. Given a PDF set and a corresponding set of weights, which describes the impact of the inclusion of new data, the prediction for a given observable after inclusion of the new data can be computed as the weighted average,

$$\langle \mathscr{O}(\{f\}) \rangle = \frac{1}{N_{\text{rep}}} \sum_{k=1}^{N_{\text{rep}}} w_k \mathscr{O}(f^k). \tag{23}$$

To simplify the use of a reweighted set, an unweighted set (i.e. a set of equiprobable replicas which incorporates the information contained in the weights) is generated according to the unweighting procedure described in [101]. The number of effective replicas of a reweighted set is measured by its Shannon Entropy [102]

$$N_{\text{eff}} \equiv \exp\left\{\frac{1}{N_{\text{rep}}} \sum_{k=1}^{N_{\text{rep}}} w_k \ln(N_{\text{rep}}/w_k)\right\},\,\,(24)$$

which corresponds to the size of a refitted equiprobable replica set containing the same amount of information. This number of effective replicas, $N_{\rm eff}$, gives an indicative measure of the optimal size of an unweighted replica set produced with the reweighting/unweighting procedure. No extra information is gained by producing a final unweighted set that has a number of replicas (significantly) larger than N_{eff} . If N_{eff} is data have great impact, however, it is unreliable to use the new reweighted set. In this case, instead, a full refit should be performed.

6 Alternatives to DGLAP Formalism

scattering data in the perturbative region $Q^2 \gtrsim$ few GeV². 772 contribution of the valence quarks At small-x and small- Q^2 DGLAP dynamics may be modiverse momentum dependent, or unintegrated PDFs (uPDFs). 777 parameters of the model.

to Bayes Theorem such that the weight of each replica, w_k , 735 The dipole picture provides an alternative approach to protonvirtual photon scattering at low x which can be applied to both inclusive and diffractive processes. In this approach, $_{\mbox{\scriptsize 738}}$ the virtual photon fluctuates into a $q\bar{q}$ (or $q\bar{q}g)$ dipole which (22) 739 interacts with the proton [103, 104]. The dipoles can be con-740 sidered as quasi-stable quantum mechanical states, which ₇₄₁ have very long life time $\propto 1/m_p x$ and a size which is not changed by scattering with the proton. The dynamics of the interaction are embedded in a dipole scattering amplitude.

> Several dipole models, which assume different behaviours of the dipole-proton cross section, are implemented in HERA-Fitter: the Golec-Biernat-Wüsthoff (GBW) dipole saturation model [28], a modified GBW model which takes into account the effects of DGLAP evolution, termed the Bartels-749 Golec-Kowalski (BGK) dipole model [30] and the colour (23) 750 glass condensate approach to the high parton density regime, named the Iancu-Itakura-Munier (IIM) dipole model [29].

> > GBW model: In the GBW model the dipole-proton cross section σ_{dip} is given by

$$\sigma_{\rm dip}(x, r^2) = \sigma_0 \left(1 - \exp\left[-\frac{r^2}{4R_0^2(x)} \right] \right),$$
 (25)

r where r corresponds to the transverse separation between the quark and the antiquark, and R_0^2 is an x-dependent scale (24) 754 parameter which represents the spacing of the gluons in the proton. R_0^2 takes the form, $R_0^2(x) = (x/x_0)^{\lambda} 1/\text{GeV}^2$, and is 756 called the saturation radius. The cross-section normalisa- σ_0 tion σ_0 , σ_0 , and σ_0 are parameters of the model fitted to the 758 DIS data. This model gives exact Bjorken scaling when the dipole size r is small.

760 BGK model: The BGK model is a modification of the GBW model assuming that the spacing R_0 is inverse to the gluon 762 distribution and taking into account the DGLAP evolution much smaller than the original number of replicas the new 763 of the latter. The gluon distribution, parametrised at some starting scale by Eq. 12, is evolved to larger scales using 765 DGLAP evolution.

766 BGK model with valence quarks: The dipole models are valid in the low-x region only, where the valence quark contribution to the total proton momentum is 5% to 15% for x769 from 0.0001 to 0.01 [105]. The inclusive HERA measure-QCD calculations based on the DGLAP [11-15] evolution 770 ments have a precision which is better than 2%. Therefore, equations are very successful in describing all relevant hard $_{771}$ HERAFitter provides the option of taking into account the

fied by saturation and other (non-perturbative) higher-twist 773 IIM model: The IIM model assumes an expression for the effects. Different approaches alternative to the DGLAP for- 774 dipole cross section which is based on the Balitsky-Kovchegov malism can be used to analyse DIS data in HERAFitter. 775 equation [106]. The explicit formula for σ_{dip} can be found These include several dipole models and the use of trans- 776 in [29]. The alternative scale parameter \tilde{R} , x_0 and λ are fitted

6.2 Transverse Momentum Dependent PDFs

QCD calculations of multiple-scale processes and complex 820 final-states can necessitate the use of transverse-momentum $_{821}$ evolution. It is defined on a grid of $50 \otimes 50 \otimes 50$ bins in dependent (TMD) [8], or unintegrated parton distribution x, k, p. The binning in the grid is logarithmic, except for and parton decay functions [107-115]. TMD factorisation 823 the longitudinal variable x for which 40 bins in logarithmic has been proven recently [8] for inclusive DIS. TMD fac- 824 spacing below 0.1, and 10 bins in linear spacing above 0.1 torisation has also been proven in the high-energy (small-x) are used. limit [116–118] for particular hadron-hadron scattering processes, like heavy flavour, vector boson and Higgs production.

120] the DIS cross section can be written as a convolution in both longitudinal and transverse momenta of the TMD parton distribution function $\mathcal{A}(x, k_t, \mu_F^2)$ with the off-shell parton scattering matrix elements as follows

$$\sigma_j(x,Q^2) = \int_x^1 dz \int d^2k_t \ \hat{\sigma}_j(x,Q^2,z,k_t) \ \mathscr{A}\left(z,k_t,\mu_F^2\right),$$
 (26)

where the DIS cross sections $\sigma_j(j=2,L)$ are related to the structure functions F_2 and F_L by $\sigma_i = 4\pi^2 F_i/Q^2$, and the hard-scattering kernels $\hat{\sigma}_i$ of Eq. 26 are k_t -dependent.

79:

814

The factorisation formula in Eq. 26 allows resummation of logarithmically enhanced small-x contributions to all orders in perturbation theory, both in the hard scattering coefficients and in the parton evolution, fully taking into account the dependence on the factorisation scale μ_F and on the factorisation scheme [121, 122].

Phenomenological applications of this approach require matching of small-x contributions with finite-x contributions. To this end, the evolution of the transverse momentum dependent gluon density A is obtained by combining the resummation of small-x logarithmic corrections [123–125] with lence quarks are treated using the method of Ref. [126] as medium-x and large-x contributions to parton splitting [11, 14, 15] according to the CCFM evolution equation [23–26].

The cross section σ_i , (j = 2, L) is calculated in a FFN scheme, using the boson-gluon fusion process ($\gamma^*g^* \to q\bar{q}$). ⁸⁴⁴ The TMD parton densities can be plotted either with HERA-The masses of the quarks are explicitly included as parameters of the model. In addition to $\gamma^* g^* o q \bar{q}$, the contribution from valence quarks is included via $\gamma^* q \to q$ by using a CCFM evolution of valence quarks [126–128].

CCFM Grid Techniques: The CCFM evolution cannot be written easily in an analytic closed form. For this reason, a MC method is employed, which is, however, time-consuming, and thus cannot be used directly in a fit program.

Following the convolution method introduced in [128, 129], the kernel $\tilde{\mathcal{A}}(x'', k_t, p)$ is determined from the MC solution of the CCFM evolution equation, and then folded with a non-perturbative starting distribution $\mathcal{A}_0(x)$

$$x\mathscr{A}(x,k_t,p) = x \int dx' \int dx'' \mathscr{A}_0(x') \widetilde{\mathscr{A}}(x'',k_t,p) \, \delta(x'x''-x)$$

$$= \int dx' \mathscr{A}_0(x') \frac{x}{x'} \, \widetilde{\mathscr{A}}(\frac{x}{x'},k_t,p),$$
(27)
$$\frac{\text{full uncertainties are estimated. The HERAFitter code is a}}{\text{HERAPDF1.0 set.}}$$

where k_t denotes the transverse momentum of the propagator gluon and p is the evolution variable.

The kernel $\tilde{\mathscr{A}}$ incorporates all of the dynamics of the

Calculation of the cross section according to Eq. 26 involves a time-consuming multidimensional MC integration, which suffers from numerical fluctuations. This cannot be In the framework of high-energy factorisation [116, 119, 829 employed directly in a fit procedure. Instead the following 830 equation is applied:

$$\sigma(x,Q^2) = \int_x^1 dx_g \mathscr{A}(x_g, k_t, p) \hat{\sigma}(x, x_g, Q^2)$$
$$= \int_x^1 dx' \mathscr{A}_0(x') \tilde{\sigma}(x/x', Q^2), \tag{28}$$

where first $\tilde{\sigma}(x',Q^2)$ is calculated numerically with a MC integration on a grid in x for the values of Q^2 used in the 833 fit. Then the last step in Eq. 28 is performed with a fast numerical Gauss integration, which can be used directly in the

836 Functional Forms for TMD parametrisation: For the starting distribution \mathcal{A}_0 , at the starting scale Q_0^2 , the following

$$x\mathscr{A}_0(x,k_t) = Nx^{-B}(1-x)^C \left(1 - Dx + E\sqrt{x}\right)$$
$$\times \exp[-k_t^2/\sigma^2], \tag{29}$$

where $\sigma^2 = Q_0^2/2$ and N, B, C, D, E are free parameters. Vadescribed in Ref. [128] with a starting distribution taken 842 from any collinear PDF and imposition of the flavour sum 843 rule at every scale p.

Fitter tools or with TMDplotter [35].

7 HERAFitter Code Organisation

 $_{\mbox{\scriptsize 847}}$ HERAFitter is an open source code licensed under the GNU general public licence. It can be downloaded from a dedicated webpage [1] together with its supporting documentaso tion and fast grid theory files (described in section 4) as-851 sociated with data files. The source code contains all the relevant information to perform QCD fits with HERA DIS 853 data as a default set. 1 The execution time depends on the fitting options and varies from 10 minutes (using "FAST" techniques as described in section 4) to several hours when

¹Default settings in HERAFitter are tuned to reproduce the central

combination of C++ and Fortran 77 libraries with mini- 891 impact of QED radiative corrections on PDFs [139]. A remal dependencies, i.e. for the default fitting options no ex- 892 cent study based on a set of PDFs determined with HERAternal dependencies are required except the QCDNUM evolu- 893 Fitter and addressing the correlated uncertainties between tion program [22]. The ROOT libraries are only required for 894 different orders has been published in [100]. An application the drawing tools and when invoking APPLGRID. Fig. 8 shows an illustration of a comparison between the inclusive NC data from 898 PDF grids from QCD analyses performed at HERA [21, HERA I with the predictions based on HERAPDF1.0 PDFs. 899 141] and at the LHC [142], using measurements from AT-The consistency of the measurements and the theory can be 500 LAS [91, 133]. These PDFs can be used to study predictions expressed by pulls, defined as the difference between data 901 for SM or beyond SM processes. Furthermore, HERAFitter and theory divided by the uncorrelated error of the data. In 902 provides the possibility to perform various benchmarking each kinematic bin of the measurement, pulls are provided 903 exercises [143] and impact studies for possible future colin units of standard deviations. The pulls are also illustrated 904 liders as demonstrated by QCD studies at the LHeC [144]. in Fig. 8.

The HERAFitter framework has been used to produce

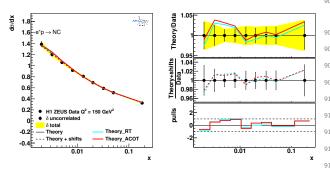

Fig. 8 An illustration of the consistency of HERA measurements [21] and the theory predictions, obtained in HERAFitter with the default drawing tool.

fast retrieval, fast evolution kernels, and the OpenMP (Open Multi-Processing) interface which allows parallel applications of the GM-VFNS theory predictions in DIS.

905 9 Summary

906 HERAFitter is an open-source platform designed for studies of the structure of the proton. It provides a unique and flexible framework with a wide variety of QCD tools to facilitate analyses of the experimental data and theoretical calculations. HERAFitter allows for direct comparisons of various theoretical approaches under the same settings, different methodologies in treating the experimental and model uncertainties can be used for benchmarking studies.

The HERAFitter code, in version 1.1.0, has sufficient 915 options to reproduce the different theoretical choices made in MSTW, CTEQ and ABM fits. This will potentially make 917 it a valuable tool for benchmarking and understanding dif-918 ferences between PDF fits. Such a study would however In HERAFitter there are also available cache options for 919 need to consider a range of further questions, such as the choices of data sets, treatments of uncertainties, input parameter values, χ^2 definitions and so forth. The progress of 922 HERAFitter is driven by the latest QCD advances in theo-923 retical calculations and in the precision of experimental data.

8 Applications of HERAFitter

871

872

The HERAFitter program has been used in a number of 927 DESY IT department for their support of the HERAFitter developexperimental and theoretical analyses. This list includes several LHC analyses of SM processes, namely inclusive Drell930 91526-CERN a, the Polish NSC project DEC-2011/03/B/ST2/00220 jet production [133], and inclusive photon production [134]. 932 Association SO-072. We also acknowledge Nathan Hartland with Luigi The results of QCD analyses using HERAFitter were also 933 Del Debbio for contributing to the implementation of the Bayesian published by HERA experiments for inclusive [21, 135] and odiscussions. heavy flavour production measurements [136, 137]. The following phenomenological studies have been performed with HERAFitter: a determination of the transverse momentum 936 References dependent gluon distribution using precision HERA data [128], an analysis of HERA data within a dipole model [138], the 937 study of the low-x uncertainties in PDFs determined from 938 the HERA data using different parametrisations [93] and the 939
