70 proton collisions demand high-precision calculations and com-71 putations to test the validity of the Standard Model (SM) and 72 factorisation in Quantum Chromodynamics (QCD). Using 73 collinear factorisation, hadron inclusive cross sections may ₇₄ be written as

$$\sigma(\alpha_{s}(\mu_{R}^{2}), \mu_{R}^{2}, \mu_{F}^{2}) = \sum_{a,b} \int_{0}^{1} dx_{1} dx_{2} f_{a}(x_{1}, \mu_{F}^{2}) f_{b}(x_{2}, \mu_{F}^{2})$$

$$\times \hat{\sigma}^{ab}(x_{1}, x_{2}; \alpha_{s}(\mu_{R}^{2}), \mu_{R}^{2}, \mu_{F}^{2}), \tag{1}$$

where the cross section σ is expressed as a convolution of Parton Distribution Functions (PDFs) f_a and f_b with the parton cross section $\hat{\sigma}^{ab}$. At Leading-Order (LO), the PDFs represent the probability of finding a specific parton a(b)in the first (second) proton carrying a fraction x_1 (x_2) of its momentum. The indices a and b in the Eq. 1 indicate the various kinds of partons, i.e. gluons, quarks and antiquarks 82 of different flavours, that are considered as the constituents $_{83}$ of the proton. The PDFs depend on factorisation scale, $\mu_{\rm F}$, 84 while the parton cross sections depend on the strong cou- $\alpha_{\rm s}$ pling, $\alpha_{\rm s}$, and the factorisation and renormalisation scales, \mathfrak{z}_{6} $\mu_{\rm F}$ and $\mu_{\rm R}$. The parton cross sections $\hat{\sigma}^{ab}$ are calculable in pQCD whereas PDFs are non-perturbative and are thus constrained by global fits to a variety of experimental data. The 89 assumption that PDFs are universal, within a particular fac-₉₀ torisation scheme [9–13], is crucial to this procedure. Recent review articles on PDFs can be found in Refs. [14, 15].

Accurate determination of PDFs as a function of x reguires large amount of hard-process experimental data, cov-94 ering a wide kinematic region and sensitive to different kinds 95 of partons. Measurements of the inclusive Neutral Current 96 (NC) and Charge Current (CC) Deep Inelastic Scattering 97 (DIS) at the *ep* collider HERA provide crucial information ₉₈ for determining the PDFs. Hard processes in pp and $p\bar{p}$ col-99 lisions at the LHC and the Tevatron, respectively, provide 100 complementary information to the DIS measurements. The PDFs are determined from χ^2 fits of the theoretical predic-11 102 tions to the data [16–20]. The rapid flow of new data from 11 103 the LHC experiments and the corresponding theoretical developments, which are providing predictions for more com-105 plex processes at increasingly higher orders, has motivated $\frac{12}{13}$ the development of a tool to combine them together in a fast, 13 107 efficient, open-source platform.

This paper describes the open-source QCD fit platform 13 109 HERAFitter which includes a set of tools designed to facilitate comprehensive global QCD analyses of pp, $p\bar{p}$ and epscattering data. It has been developed for the determination $\frac{1}{14}$ $\frac{1}{12}$ of PDFs and the extraction of fundamental QCD parameters 14 113 such as the heavy quark masses and the strong coupling con-15 114 stant. It also provides a common platform for comparison of different theoretical approaches. Furthermore, it can be used for direct tests of the impact of new experimental data on the PDFs and on the SM parameters.

This paper is organised as follows. The structure and overview of HERAFitter are presented in Section 2. In Section 3 the various processes available in HERAFitter and the corresponding theoretical calculations, performed within the framework of collinear factorisation and the DGLAP [21– 25] formalism, are discussed. In Section 4 tools for fast calculations of the theoretical predictions used in HERAFitter are presented. In Section 5 the methodology of determining PDFs through fits based on various χ^2 definitions is explained. In particular, different treatment of correlated experimental uncertainties are presented. Alternative approaches to the DGLAP formalism are presented in Section 6. The HERAFitter code organisation is discussed in Section 7, specific applications of the package are given in Section 8 and a summary is presented in Section 9.

2 The HERAFitter Structure

119

In this section the functionality of HERAFitter is described. A block diagram in Fig 1 illustrates the schamatical view of the HERAFitter functionality which can be divided into four main blocks:

145 [16–20]. However, improvements in precision of PDFs require additional constraints on the gluon and quark distributions at high-x, better understanding of heavy quark distributions and decomposition of the light-quark sea. For these purposes, the measurements of the fixed-target experiments, Tevatron and LHC are of particular importance. The processes that are currently available in HERAFitter framework are listed in Tab. 1.

153 Theory: Predictions for cross section of different processes are obtained using the factorisation approach (Eq. 1). The PDFs are parametrised at a starting input scale Q_0^2 by a chosen functional form with a set of free parameters **p**. These PDFs are evolved to the scale of the measurement Q^2 , $Q^2 >$ Q_0^2 . The evolution follows either DGLAP [21–25] (as implemented in QCDNUM [26]) or CCFM [27-30] (as implemented in uPDFevolv [31]). The prediction of a cross section of a particular process is obtained by a convolution of the evolved PDFs and the partonic cross section, calculated at a certain order in QCD with a appropriate theory calculation (as listed in Tab. 1). Alternatively, predictions using dipole models [32–34] can be also obtained.

cesses are implemented in the HERAFitter package includ- 166 QCD analysis: The PDFs are determined by the least square ing the full information on their uncorrelated and correlated $_{167}$ fit, minimising the χ^2 function, formed using the input data uncertainties. HERA data are sensitive to light quark and 168 and theory predictions, with the MINUIT [35] program. 3 Theoretical formalism using DGLAP evolution

In this section the theoretical formalism based on DGLAP [21–25] evolution is described.

dependence or "evolution" of the PDFs can be predicted by 230 is related to their difference, $xF_3 \approx x \sum 2e_q a_q (q - \overline{q})$ (where the renormalisation group equations. By requiring that phys- a_q is the axial-vector quark coupling and a_q the quark elecical observables are independent of μ_F , a representation of 232 tric charge) and F_L vanishes. At higher orders, terms related parton evolution in terms of the DGLAP equations:

$$\frac{d f_a(x, \mu_F^2)}{d \log \mu_F^2} = \sum_{b=a\bar{a}, e} \int_x^1 \frac{dz}{z} P_{ab} \left(\frac{x}{z}; \mu_F^2\right) f_b(z, \mu_F^2), \tag{2}$$

where the functions P_{ab} are the evolution kernels or splitting functions, which represent the probability of finding parton a in parton b. They can be calculated as a perturbative expansion in α_s . Once PDFs are determined at the initial scale Q_0^2 ,

or a covariance matrix method as described in section 5.2. 195 their evolution to any other scale $Q^2 > Q_0^2$ is entirely deter-198 ternative approaches to DGLAP evolution, valid in different 199 kinematic regimes, are also implemented in HERAFitter

201 3.1 Deep Inelastic Scattering and Proton Structure

The formalism that relates the DIS measurements to pQCD and the PDFs has been described in detail in many extensive reviews (see e.g. Ref. [41]) and it is only briefly summarised here. DIS is the process where a lepton scatters off the partons in the proton by a virtual exchange of a NC (neutral current) or CC (charged current) vector boson and, as a result, a scattered lepton and a multi-hadronic final state are produced. The common DIS kinematic variables are the scale of the process Q^2 , the absolute squared four-momentum of the exchange boson, Bjorken x, which can be related in the parton model to the fraction of momentum carried by the struck quark, and the inelasticity y. These are related by $y = Q^2/sx$, where s is the squared centre-of-mass (c.o.m.) energy.

The NC cross section can be expressed in terms of gener-216 alised structure functions:

$$\frac{d^2 \sigma_{NC}^{e^{\pm} p}}{dx dQ^2} = \frac{2\pi \alpha^2}{xQ^4} \cdot \sigma_{r,NC}^{e^{\pm} p},\tag{3}$$

$$\sigma_{rNC}^{e^{\pm}p} = Y_{+}\tilde{F}_{2}^{\pm} \mp Y_{-}x\tilde{F}_{3}^{\pm} - y^{2}\tilde{F}_{L}^{\pm},\tag{4}$$

where $Y_{\pm} = 1 \pm (1 - y)^2$ and the electromagnetic coupling 218 constant α , the photon propagator and a helicity factor are absorbed in the definition of the reduced cross section σ_r . The generalised structure functions \tilde{F} can be written as linear combinations of the proton structure functions F^{γ} , $F^{\gamma Z}$ and F^{Z} , which are associated to pure photon exchange terms, 223 photon-Z interference terms and pure Z exchange terms, respectively. The structure function \tilde{F}_2 is the dominant contribution to the cross section, $x\tilde{F}_3$ becomes important at high Q^2 and \tilde{F}_L is sizable only at high y. In the framework of pQCD the structure functions are directly related to the PDFs. i.e. in leading order (LO) F_2 is the weighted momentum sum A direct consequence of factorisation (Eq. 1) is that scale 229 of quark and anti-quark distributions, $F_2 \approx x \sum e_a^2 (q + \overline{q})$, xF_3 to the gluon density distribution $(\alpha_s g)$ appear, in particular F_L is strongly related to the low-x gluon.

235 The inclusive CC ep cross section, analogous to the NC (2) 236 case, can be expressed in terms of another set of structure functions, \tilde{W} ::

$$\frac{d^2 \sigma_{CC}^{e^{\pm} p}}{dx dQ^2} = \frac{1 \pm P}{2} \frac{G_F^2}{2\pi x} \left[\frac{M_W^2}{M_W^2 + Q^2} \right] \cdot \sigma_{r,CC}^{e^{\pm} p}$$
 (5)

$$\sigma_{r,CC}^{e^{\pm}p} = Y_{+}\tilde{W}_{2}^{\pm} \mp Y_{-}x\tilde{W}_{3}^{\pm} - y^{2}\tilde{W}_{L}^{\pm}, \tag{6}$$

 α_s , the CC e^+p and e^-p cross sections are sensitive to dif- 286 tions at Next-to-Next-to Leading Order (NNLO) are proferent combinations of the quark flavour densities.

$$\sigma_{r,CC}^{e^+p} \approx x[\overline{u} + \overline{c}] + (1 - y)^2 x[d + s], \tag{7}$$

$$\sigma_{r,CC}^{e^{-p}} \approx x[u+c] + (1-y)^2 x[\overline{d} + \overline{s}], \tag{8}$$

Here U and D denote the sum over up- and down-type quarks; $_{^{292}}$ precision of the mass definition. the latter include also strange and beauty quarks and the former charm quarks.

ferred to as coefficient functions.

beauty) production and the chosen values of their masses be- 301 are presented below: comes important. There are different approaches to the treatment of heavy quark production that would be equivalent if calculations could be carried out to all orders in α_s , but which differ at finite order. Several variants of these schemes are implemented in HERAFitter and they are briefly discussed below.

Zero-Mass Variable Flavour Number (ZM-VFN)[2]: In this scheme, the heavy quarks appear as partons in the proton at Q^2 values above $\sim m_h^2$ (heavy quark mass) and the heavy quarks are then treated as massless in both the initial and final states of the hard scattering process. The lowest order process is the scattering of the lepton off the heavy quark via (electroweak) boson exchange. This scheme is expected to be reliable in the region with $Q^2 \gg m_h^2$. In HERAFitter this scheme is available for the DIS structure function calculation via the interface to the QCDNUM [26] package, thus it benefits from the fast QCDNUM convolution engine.

Fixed Flavour Number (FFN)[3-5]: In this scheme only the gluon and the light quarks are considered as partons within the proton and massive quarks are produced perturbatively in the final state. The lowest order process is the heavy quark- $_{_{324}}$ antiquark pair production via boson-gluon fusion. In HERA-Fitter this scheme can be accessed via the QCDNUM implementation or through the interface to the open-source code OPENQCDRAD [42], as implemented by the ABM group. This scheme is reliable for $Q^2 \sim m_h^2$. In QCDNUM, the calculation of 327 3.2 Electroweak Corrections to DIS the heavy quark contributions to DIS structure functions are available at Next-to-Leading-Order (NLO) and only electro- 328 Calculations of higher-order electroweak corrections to DIS magnetic exchange contributions are taken into account. In 329 scattering at HERA are available in HERAFitter in the onthe OPENQCDRAD implementation the heavy quark contribu- 330 shell scheme. In this scheme the gauge bosons masses M_W tions to CC structure functions are also available and, for the $_{331}$ and M_Z are treated as basic parameters together with the top, NC case, the QCD corrections to the massive Wilson coef- 332 Higgs and fermion masses. These electroweak corrections

where P represents the lepton beam polarisation. At LO in 285 the NC case, the QCD corrections to the coefficient funcvided at the best currently known approximation [43]. The 288 OPENQCDRAD implementation also uses the running heavyquark mass [44] in the $\overline{\rm MS}$ scheme. This scheme has the ad-(8) 290 vantage of reducing the sensitivity of the DIS cross sections 291 to higher order corrections, and improving the theoretical

293 General-Mass Variable Flavour Number (GM-VFN)[6]: In Beyond LO, the QCD predictions for the DIS structure $_{294}$ these schemes, heavy quark production is treated for $Q^2 \sim$ functions are obtained by convoluting the PDFs with appro- $_{295}$ m_h^2 in the FFN scheme and for $Q^2 \gg m_h^2$ in the massless priate hard-process scattering matrix elements, which are re- 296 scheme with a suitable interpolation inbetween. The details 297 of this interpolation differ between different implementa-The DIS measurements span a large range of Q^2 from $_{298}$ tions. The PDF groups that use GM-VFN schemes are MSTW, few GeV^2 to about 10^5 GeV^2 , crossing heavy-quark mass $_{299}$ CT(CTEQ), NNPDF, and HERAPDF. HERAFitter implethresholds, thus the treatment of heavy quark (charm and 300 ments different variants of the GM-VFN scheme and they

- GM-VFN Thorne-Roberts scheme: The Thorne-Roberts (TR) scheme [45] was designed to provide a smooth transition from the massive FFN scheme at low scales $Q^2 \sim m_h^2$ to the massless ZM-VFNS scheme at high scales $Q^2 \gg m_h^2$. However, the original version was technically difficult to implement beyond NLO, and was updated to the TR' scheme [46]. There are two different variants of the TR' schemes: TR' standard (as used in MSTW PDF sets [16, 46]) and TR' optimal [47], with a smoother transition across the heavy quark threshold region. Both variants are accessible within the HERAFitter package at LO, NLO and NNLO.
- GM-VFN ACOT scheme: The Aivazis-Collins-Olness-Tung (ACOT) scheme belongs to the group of VFN factorisation schemes that use the renormalisation method of Collins-Wilczek-Zee (CWZ) [48]. This scheme unifies the low scale $Q^2 \sim m_h^2$ and high scale $Q^2 > m_h^2$ regions with a smooth interpolation across the full energy range. Within the ACOT package, different variants of the ACOT scheme are available: ACOT-Full [49], S-ACOT- χ [50, 51], ACOT-ZM [49], $\overline{\text{MS}}$ at LO and NLO. For the longitudinal structure function higher order calculations are also available. A comparison of PDFs extracted from the QCD fits to the HERA data with the TR' and ACOT-Full schemes is illustrated in Fig. 3 (taken from [40]).

319

ficients at Next-to-Next-to Leading Order (NNLO) and, for 333 are based on the EPRC package [52]. The code calculates the

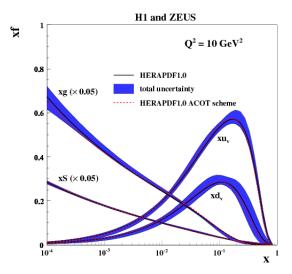

Fig. 3 Overview showing the u- and d-valence, the total sea (scaled), where $\Phi(x_{IP},t)$ are the Reggeon and Pomeron fluxes. The and gluon (scaled) PDFs of the NLO HERAPDF1.0 set [40] with their using the k-factor technique (red).

running of the electromagnetic coupling α using the most recent parametrisation of the hadronic contribution [53], as well as an older version from Burkhard [54].

3.3 Diffractive PDFs

Diffractive parton distributions (DPDFs) can be determined from QCD fits to diffractive cross sections in a similar way to the determination of the standard PDFs. About 10% of deep inelastic interactions at HERA are diffractive, such that the interacting proton stays intact $(ep \rightarrow eXp)$. The proton is well separated from the rest of the hadronic final state by a large rapidity gap. This is interpreted as the dissociation of the virtual photon into hadronic system X with an invariant mass much smaller than the photon-proton c.o.m. energy $W = ys - Q^2 + m_p^2(1-y)$, where m_p is proton's mass. Such a process is assumed to be mediated by the exchange of a hard Pomeron or a secondary Reggeon with vacuum quantum numbers. This factorisable pomeron picture has proved remarkably successful in the description of most of $_{376}$ where S is the squared c.o.m. beam energy, the parton mo-352 the diffractive data.

matic variables are needed to describe the diffractive pro- 379 cross section. cess. These are the squared four-momentum transfer of the 380 exchange Pomeron or Reggeon, t, and the mass M_X of the M_X of the orresponding CC triple differential cross section has diffractively produced final state. In practice, the variable 382 the form: M_X is often replaced by dimensionless quantity $\beta = \frac{Q^2}{M_X^2 + Q^2 - t}$. In models based on a factorisable pomeron, β may be viewed at LO as the fraction of the pomeron longitudinal momentum which is carried by the struck parton, $x = \beta x_{IP}$.

For the inclusive case, the diffractive cross-section reads as:

$$\frac{d\sigma}{d\beta dQ^2 dx_{IP} dt} = \frac{2\pi\alpha^2}{\beta Q^4} \left(1 + (1-y)^2\right) \overline{\sigma}^{D(4)}(\beta, Q^2, x_{IP}, t)$$
 (9)

with the "reduced cross-section":

$$\overline{\sigma}^{D(4)} = F_2^{D(4)} - \frac{y^2}{1 + (1 - y)^2} F_L^{D(4)}.$$
 (10)

Substituting $x = x_{IP}\beta$ we can relate Eq. 9 to the standard DIS formula. In this way, the diffractive structure functions can be expressed as convolutions of calculable coefficient functions with the diffractive quark and gluon distribution functions, which in general depend on x_{IP} , Q^2 , β , t.

The diffractive PDFs in HERAFitter [55, 56] are implemented as a sum of two factorised contributions:

$$\Phi_{IP}(x_{IP},t) f_a^{Pom}(\beta,Q^2) + \Phi_{IR}(x_{IP},t) f_a^{IR}(\beta,Q^2), \qquad (11)$$

and gluon (scaled) PDFs of the NLO HERAPDF1.0 set [40] with their total uncertainty at the scale of $Q^2 = 10 \text{ GeV}^2$ obtained using the TR' scheme and compared to the PDFs obtained with the ACOT scheme of PDFs, f_a^{IR} are fixed as those of the pion, while the PDFs obtained with the ACOT scheme of PDFs, f_a^{IR} , can be obtained from a fit to the data.

3.4 Drell-Yan Processes in pp or $p\bar{p}$ Collisions

Drell-Yan process provides further valuable information about PDFs. In pp and $p\bar{p}$ scattering, the Z/γ^* and W production probe bi-linear combinations of quarks. Complementary in-365 formation on the different quark densities can be obtained from the W asymmetry (d, u) and their ratio, the ratio of the W and Z cross sections (sensitive to the flavour composition of the quark sea, in particular to the s-quark density), and associated W and Z production with heavy quarks (sensitive to s- and c-quark densities). Measurements at large boson $p_T \gtrsim M_{W,Z}$ are potentially sensitive to the gluon den-372 sity [57].

At LO the DY NC triple differential cross section in invariant mass M, boson rapidity y and lepton scattering angle $\cos \theta$ in the parton c.o.m. frame can be written as [58, 59]:

$$\frac{d^3\sigma}{dMdyd\cos\theta} = \frac{\pi\alpha^2}{3MS} \sum_{q} \hat{\sigma}^q(\cos\theta, M) \times \left[f_q(x_1, Q^2) f_{\bar{q}}(x_2, Q^2) + (q \leftrightarrow \bar{q}) \right], \quad (12)$$

mentum fractions are given by $x_{1,2} = \frac{M}{\sqrt{S}} \exp(\pm y), f_q(x_1, Q^2)$ In addition to the usual DIS variables x, Q^2 , extra kine- $_{378}$ are the PDFs, and $\hat{\sigma}^q$ is the parton-parton hard scattering

$$\frac{d^{3}\sigma}{dMdyd\cos\theta} = \frac{\pi\alpha^{2}}{48S\sin^{4}\theta_{W}} \frac{M^{3}(1-\cos\theta)^{2}}{(M^{2}-M_{W}^{2}) + \Gamma_{W}^{2}M_{W}^{2}} \times \sum_{q_{1},q_{2}} V_{q_{1}q_{2}}^{2} f_{q_{1}}(x_{1},Q^{2}) f_{q_{2}}(x_{2},Q^{2}), \tag{13}$$

where $V_{q_1q_2}$ is the Cabibbo-Kobayashi-Maskawa (CKM) quarko mixing matrix and M_W and Γ_W are the W boson mass and Γ_W tions and single-top cross sections can be used, for example, decay width, respectively.

calculation of integrated cross sections. In both NC and CC 434 tion are available to NLO accuracy using MCFM. expressions the PDFs depend only on boson rapidity y and invariant mass M, while the integral in $\cos \theta$ can be solved analytically even for the case of realistic kinematic cuts.

Beyond LO, the calculations can no longer be done quickly and MC techniques are often employed. Currently, the predictions for W and Z/γ^* production are available up to NNLO⁴³⁷ equally good accuracy in order to maximise their impact in and the predictions for W, Z in association with heavy flavour 438 PDF fits. Perturbative calculations, however, get more and quarks is available to NLO. There are several possibilities for obtaining the theoretical predictions for DY production in HERAFitter.

The NLO and NNLO calculations are computing power and time consuming and k-factor or fast grid techniques must be employed (see section 4 for details), interfaced to programs such as MCFM [60-62], available for NLO calculations, or FEWZ [63] and DYNNLO [64] for NLO and NNLO.

3.5 Jet Production in ep and pp or $p\bar{p}$ Collisions

397

The cross section for production of high-transverse-momentum hadronic jets is sensitive to the high-x gluon PDF (see e.g. 4.1 k-factor Technique Ref. [16]) therefore this process can be used to improve the determination of the gluon PDF, which is particularly im- 452 The k-factors are defined as the ratio of the prediction of a portant for Higgs production and searches for new physics. 453 higher-order (slow) pQCD calculation to a lower-order (fast) Jet production cross sections are currently known only to 454 calculation. Because the k-factors depend on the phase space NLO, although calculations for higher-order contributions 455 probed by the measurement, they have to be stored in a table to jet production in proton-proton collisions are now quite 456 including dependence on the relevant kinematic variables. advanced [65–67]. Within HERAFitter, the NLOJet++ pro- $_{457}$ Before the start of a fitting procedure, the table of k-factors gram [68, 69] may be used for calculations of jet production. 458 has to be computed once for a given PDF with the time con-Similarly to the DY case, the calculation is very demanding 459 suming higher-order code. 435 4 Computational Techniques

436 Precise measurements require theoretical predictions with 439 more involved with order due to an increasing number of 440 Feynman diagrams. Nowadays even the most advanced perturbative techniques in combination with modern computing hardware do not lead to sufficiently small turn-around times. The direct inclusion of computationally demanding higherorder calculations into iterative fits therefore is not possible. Relying on the fact that a full repetition of the perturbative calculation for arbitrary changes in input parameters is not necessary at each iteration step, two methods have been developed to resolve this problem: the techniques of k-factors and fast grids. Both are available in HERAFitter and described as follows.

This procedure, however, neglects the fact that the kfactors can be PDF dependent, as a consequence, they have to be re-evaluated for the newly determined PDF at the end of the fit for the consistency check. Usually, the fit is repeated until input and output k-factors have converged. In summary, this technique avoids iteration of the higher-order At the LHC top-quark pairs $(t\bar{t})$ are produced at hadron col-468 calculation at each step, but still requires a couple of repetitions depending on the analysis.

An implementation of k-factor technique in HERAFitter the gluon density at medium to high values of x, on α_s and α_{71} is used for the fast approximation of the time-consuming on the top-quark mass, m_t [70]. Precise predictions for the 472 GM-VFN schemes for heavy quarks in DIS. "FAST" heavytotal $t\bar{t}$ cross section are available to full NNLO [71]. They 473 flavour schemes are implemented with k-factors defined as can be computed within HERAFitter via an interface to the 474 the ratio of calculations at the same perturbative order but program HATHOR [72]. Differential $t\bar{t}$ cross section predic-475 for massive vs. massless quarks, e.g. NLO (massive)/NLO ing PDF and hence, the "FAST" heavy flavour schemes should

only be used for quick checks, i.e. full heavy flavour schemes 528 are normally recommended. For the ACOT case, due to long 529 computation time, the k-factors are used in the default settings in HERAFitter.

531

532

533

534

4.2 Fast Grid Techniques

Fast grid techniques exploit the fact that iterative PDF fitting procedures do not impose completely arbitrary changes 537 to the types and shapes of the parameterised functions that represent each PDF. Instead, it can be assumed that a generic PDF can be approximated by a set of interpolating functions with a sufficient number of support points. The accuracy of this approximation can be checked and optimised in various ways with the simplest one being an increase in the number 543 of support points. Having ensured that the approximation 544 bias is negligibly small compared to the experimental and 545 theoretical accuracy for all practical purposes, this method 546 can be used to perform the time consuming higher-order 547 calculations (Eq. 1) only once for the set of interpolating $_{548}$ functions. Further iteration of a cross section evaluation for a particular PDF set is fast and implies only sums over the set of interpolators multiplied by factors depending on the PDF. The approach applies equally for the cross sections of processes involving one or two hadrons in the initial state as 553 well as to their renormalisation and factorisation scale variation.

This technique was pioneered in the fastNLO project $[77]_{556}$ to facilitate the inclusion of notoriously time consuming jet 557 cross sections at NLO into PDF fits. The APPLGRID [78] 558 project developed an alternative method and, in addition to 559 jets, extended its applicability to other scattering processes, such as DY, heavy quark pair production is association with $_{561}$ boson production, etc. While differing in their interpolation 562 and optimisation strategies, both packages construct tables 563 with grids for each bin of an observable in two steps: in the first step, the accessible phase space in the parton momentum fractions x and the renormalisation and factorisation scales μ_R and μ_F is explored in order to optimise the table size. The second step consists of the actual grid filling for the requested observables. Higher-order cross sections can then be restored very efficiently from the pre-produced grids while varying externally provided PDF sets, μ_R and μ_F , or the strong coupling $\alpha_s(\mu_R)$. The approach can in principle be extended to arbitrary processes, but requires to establish an interface between the higher-order theory programs and the fast interpolation frameworks. Work in that direction is ongoing for both packages and described in more details in the following:

in hadron-hadron collisions at NLO [69, 80]. To demonstrate the applicability to higher-orders, threshold corrections at 2-loop order, which approximate the NNLO for the inclusive jet cross section, have been included into the framework [81] following Ref. [82].

The latest version of fastNLO convolution program [83] allows for a creation of tables where renormalisation and factorisation scales can be varied as a function of two pre-defined observables, e.g. jet transverse momentum p_{\perp} and Q for DIS. The fastNLO code is available online [84] where also the jet cross-section grids computed for kinematics of various experiments can be downloaded. Dedicated fastNLO libraries and tables with theory predictions for comparison to particular cross section measurements are included into the HERAFitter package. For the HERAFitter implementation, the evaluation of the strong coupling constant is taken consistently with the PDF evolution from the QCDNUM code.

In the APPLGRID package [78, 85], in addition to the jet cross sections from NLOJet++ in $pp(\bar{p})$ and DIS processes, the calculations of DY production are also implemented. The look-up tables (grids) can be generated with the customised versions of the MCFM parton level DY generator [60-62]. The variation of the renormalisation and factorisation scales is possible a posteriori, when calculating theory predictions with the APPLGRID tables, and independent variation of the strong coupling constant is also allowed. For NNLO predictions in HERAFitter, the k-factors technique can be also applied within the APPLGRID framework.

The HERAFitter interface to APPLGRID was in particular used by the ATLAS collaboration to extract the strange quark density of the proton from W and Z cross sections [86]. An illustration of ATLAS PDFs extracted employing these techniques is displayed in Fig. 4 together with the comparison to global PDF sets CT10 [17] and NNPDF2.1 [18] (taken from [86]).

565 5 Fit Methodology

Performing a QCD analysis it is necessary to check stability of the results w.r.t. different assumptions, e.g. the functional parametrisation form, the heavy quarks mass values, alternative theoretical calculations, method of minimisation, interpretation of uncertainties, etc. It is also desirable to be able to discriminate or quantify the effect of the chosen ansatz, 572 ideally within a common framework, and HERAFitter is optimally designed for such tests. The methodology employed 574 by HERAFitter relies on a flexible and modular framework The fastNLO project [77] has been interfaced to the 575 that allows for independent integration of the state-of-the-art NLOJet++ program [68] for the calculation of jet pro- 576 techniques, either related to the inclusion of a new theoretiduction in DIS [79] as well as 2- and 3-jet production 577 cal calculation, or of new approaches to treat uncertainties.

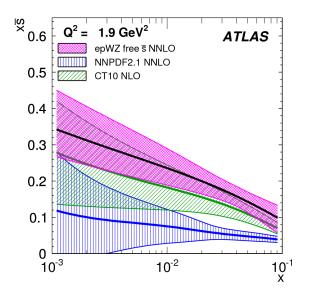

Fig. 4 The strange antiquark density versus x for the ATLAS epWZ free sbar NNLO fit [86] (magenta band) compared to predictions from NNPDF2.1 (blue hatched) and CT10 (green hatched) at Q^2 = 1.9 GeV². The ATLAS fit was performed using a k-factor approach for NNLO corrections.

In this section we describe the available option for the fit methodology in HERAFitter. In addition, as an alternative approach to a complete OCD fit, the Bayesian reweighting method, which is also available in HERAFitter, is described.

5.1 Functional Forms for PDF Parametrisation

Standard Polynomials: The standard polynomial form is most₁₈ commonly used by the PDF groups. A polynomial func- 619 HERA data using different parametrisatons were studied in tional form is used to parametrise the x-dependence of the 620 Ref. [87]. Fig. 5 (taken from [87]) shows the comparison of PDFs, where index *j* denotes each parametrised PDF:

$$xf_j(x) = A_j x^{B_j} (1 - x)^{C_j} P_i(x).$$
(14)

and xd_v , the gluon distribution xg, and the u-type and d- 624 cess external PDF sets, which can be used to compute thetype sea as constrained by HERA data alone, $x\bar{U}$, $x\bar{D}$, where 625 oretical predictions for the various processes of interest as $x\bar{U}=x\bar{u}, x\bar{D}=x\bar{d}+x\bar{s}$ at the starting scale. The form of 626 implemented in HERAFitter. This is possible via an inpolynomials $P_i(x)$ depend on the style and is defined as a 627 terface to LHAPDF [37, 38] providing access to the global steerable parameter. The form $(1 + \varepsilon_j \sqrt{x} + D_j x + E_j x^2)$ is 628 PDF sets. HERAFitter also allows to evolve PDFs from used for the HERAPDF [40] style with additional constraints 629 LHAPDF with QCDNUM using the corresponding grids as a relating to the flavour decomposition of the light sea. For the 630 starting scale. Fig. 6 illustrates the comparison of the PDFs CTEQ style, $P_i(x)$ takes the form $e^{a_3x}(1+e^{a_4}x+e^{a_5}x^2)$ and, 631 accessed from LHAPDF as produced with the drawing tools in contrast to polynomial form, is positive by construction. 632 available in HERAFitter.

OCD number and momentum sum rules are used to determine the normalisations A for the valence and gluon distributions, and the sum rule integrals are solved analytically.

Bi-Log-Normal Distributions: The parametrisation is motivated by multi-particle statistics and holds the following functional form:

$$x f_i(x) = a_i x^{p_j - b_j \log(x)} (1 - x)^{q_j - d_j \log(1 - x)}.$$
 (15)

This function can be regarded as a generalisation of the standard polynomial form described above, however, numerical integration of Eq. 15 is required in order to satisfy the QCD sum rules.

Chebyshev Polynomials: A flexible parametrisation employed for the gluon and sea distributions and based on the Chebyshev polynomials. For better modelling the low-x asymptotic of those PDFs, the polynomial of the argument log(x)are considered. Furthermore, the PDFs are multiplied by the factor of (1-x) to ensure that they vanish as $x \to 1$. The 610 resulting parametric form reads

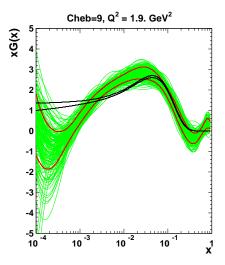

$$xg(x) = A_g (1 - x) \sum_{i=0}^{N_g - 1} A_{g_i} T_i \left(-\frac{2 \log x - \log x_{\min}}{\log x_{\min}} \right), \quad (16)$$

$$xS(x) = (1-x) \sum_{i=0}^{N_S-1} A_{S_i} T_i \left(-\frac{2\log x - \log x_{\min}}{\log x_{\min}} \right),$$
 (17)

where T_i are the first-type Chebyshev polynomials of the order i. The normalisation factor A_g is defined from the mo-613 mentum sum rule which can be evaluated analytically. The The PDFs are parametrised using several predefined func- $_{614}$ values of $N_{g,S}$ up to 15 are allowed, however, already starttional forms and different flavour decompositions. In HERAFittering from $N_{g,S} \geq 5$ the fit quality is already similar to the following functional forms to parametrise PDFs can be used: standard-polynomial parametrisation with a similar number of parameters.

5.2 Representation of χ^2

The PDF parameters are determined in HERAFitter by minimisation of the χ^2 function taking into account correlated and uncorrelated measurement uncertainties. There are various forms of χ^2 differing by method used to include the experimental uncertainties, e.g. using covariance matrix or 676 Any source of the measurement systematic uncertainty can providing nuisance parameters to encode dependence of each 677 be treated as additive or multiplicative. The statistical uncersystematic source for each measurement data point, different 678 tainties can be included as additive or Poisson. Minimisation

scaling options, etc. The options available in HERAFitter are following.

Covariance Matrix Representation: For a data point μ_i with a corresponding theory prediction m_i , the χ^2 function can be expressed in the following form:

$$\chi^{2}(m) = \sum_{i,k} (m_{i} - \mu_{i}) C_{ik}^{-1}(m_{k} - \mu_{k}), \tag{18}$$

where the experimental uncertainties are given in a form of covariance matrix $C_{i,k}$ for measurements in bins i and k. The covariance matrix C_{ik} is given by the sum of statistical, uncorrelated and correlated systematic contributions:

$$C_{ik} = C_{ik}^{stat} + C_{ik}^{uncor} + C_{ik}^{sys}. (19)$$

With this representation the effect of a certain systematic source of the uncertainty cannot be distinguished from others.

Nuisance Parameters Representation: For the case when systematic uncertainties are separated by sources the χ^2 form is expressed as

$$\chi^{2}(m,b) = \sum_{i} \frac{\left[\mu_{i} - m_{i}\left(1 - \sum_{j} \gamma_{j}^{i} b_{j}\right)\right]^{2}}{\delta_{i,\text{unc}}^{2} m_{i}^{2} + \delta_{i,\text{stat}}^{2} \mu_{i} m_{i}\left(1 - \sum_{j} \gamma_{j}^{i} b_{j}\right)} + \sum_{j} b_{j}^{2},$$
(20)

where, $\delta_{i,\mathrm{stat}}$ and $\delta_{i,\mathrm{unc}}$ are relative statistical and uncorrelated systematic uncertainties of the measurement i. Further, γ_i^i quantifies the sensitivity of the measurement to the correlated systematic source j. The function χ^2 depends in addition on the set of systematic nuisance parameters b_i . This definition of the χ^2 function assumes that systematic uncertainties are proportional to the central prediction values (multiplicative errors), whereas the statistical uncertainties scale with the square root of the expected number of events.

During the χ^2 minimisation, the nuisance parameters b_i and the PDFs are determined.

Mixed Form Representation: In some cases, the statistical and systematic uncertainties of experimental data are provided in different forms. For example, the correlated experimental systematic uncertainties are available as nuisance parameters but the bin-to-bin statistical correlations are given in a form of covariance matrix. HERAFitter offers possibilities to include also the mixed form of treating statistical, uncorrelated and correlated systematic uncertainties.

with respect to nuisance parameters is performed analyti- 729 cally, however for more detailed studies of correlations individual nuisance parameters can be included in the MINUIT minimisation.

Three distinct methods for propagating experimental uncertainties to PDFs are implemented in HERAFitter and reviewed here: the Hessian, Offset, and Monte Carlo method.

Hessian (Eigenvector) method: The PDF uncertainties reflecting the uncertainties in experimental data are estimated by examining the shape of χ^2 in the neighbourhood of the minimum [88]. Following approach of Ref. [88], the Hessian matrix is defined by the second derivatives of χ^2 on the fitted PDF parameters. The matrix is diagonalised and the Hessian eigenvectors are computed. Due to orthogonality, these vectors correspond to statistically independent sources of the uncertainties in the PDFs obtained.

Offset method: The Offset method [89] uses the χ^2 function for the central fit for which only uncorrelated uncertainties are taken into account. The goodness of the fit can no longer be judged from the χ^2 since correlated uncertainties are ignored. The correlated uncertainties are propagated into the PDF uncertainties performing the variants of fit with the experimental data varied by $\pm 1\sigma$ from the central value for each systematic source. Since the resulting deviation of the PDF parameters from the ones obtained in the central fit are statistically independent, they are combined in quadrature to arrive at the total PDF systematic uncertainty.

In most cases, the uncertainties estimated by the offset method are larger than those from the Hessian method.

Monte Carlo method: The Monte-Carlo technique [90, 91] can be used to determine PDF uncertainties. The uncertainties are estimated using the pseudo-data replicas (typically > 100) randomly generated from the measurement central values and their systematic and statistical uncertainties taking into account all point-to-point correlations. The QCD fit is performed for each replica and the PDF central values with their experimental uncertainties are estimated using distribution of the PDF parameters over these fits, i.e. the mean values and standard deviations over the replicas.

The MC method was checked against the standard error estimation of the PDF uncertainties obtained by the Hessian method. A good agreement was found between 739 5.4 Treatment of the Theoretical Input Parameters the methods once the Gaussian distribution of statistic

ilar findings were reported by the MSTW global analysis [92].

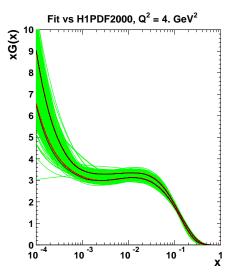

Fig. 7 Comparison between the standard error calculations as employed by the Hessian approach (black lines) and the MC approach (with more than 100 replicas) assuming Gaussian distribution for uncertainty distributions, shown here for each replica (green lines) together with the evaluated standard deviation (red lines) [36]. The black lines in the figure are mostly covered by the red lines.

Since the MC method requires large number of replicas, the eigenvector representation is often more practical to represent PDF uncertainties. As it was illustrated by [93], it is possible to transform MC to eigenvector representation. Tools to perform this transformation are provided with HERAFitter and were recently employed to obtain correlated sets of PDFs at different perturbative order [94].

The nuisance parameter representation of χ^2 in Eq. 20 is derived assuming symmetric experimental errors, however, the published systematic uncertainties are rather often asymmetric. HERAFitter provides the possibility to use asymmetric systematic uncertainties. The implementation relies on the assumption that asymmetric uncertainties can be described by a parabolic function and the nuisance parameter in Eq. 20 is modified as follows

$$\gamma_j^i \to \omega_j^i b_j + \gamma_j^i,$$
 (21)

where the coefficients ω_i^i , γ_i^i are defined by the up and down values of the systematic uncertainties, S_{ii}^{\pm}

$$\omega_{j}^{i} = \frac{1}{2} \left(S_{ij}^{+} + S_{ij}^{-} \right), \qquad \gamma_{j}^{i} = \frac{1}{2} \left(S_{ij}^{+} - S_{ij}^{-} \right).$$
 (22)

and systematic uncertainties is assumed in the MC ap- 740 The results of a QCD fit depend not only on the input data proach [36]. This comparison is illustrated in Fig. 7. Sim- 741 but also on the input parameters used in the theoretical calculations. Nowadays, the PDF groups address the impact of the choices of theoretical parameters by providing alternative PDFs with different choices of the mass of the charm quarks, m_c , mass of the bottom quarks, m_b , and the value of $\alpha_{\rm s}(M_{\rm Z})$. Another important issue is the choice of the functional form for the PDFs at the starting scale and the value of the starting scale itself. HERAFitter provides possibility of different user choices of various input parameters of the theory.

5.5 Bayesian Reweighting Techniques

As an alternative to performing a full QCD fit, HERAFitter allows to assess the impact of including new data in an existing fit using the Bayesian Reweighting technique. The method provides a fast estimate of the impact of new data on 768 which corresponds to the size of a refitted equiprobable repliveloped [92]. The latter is based on generating replica set 775 $N_{\rm eff}$. by introducing Gaussian fluctuations on the central PDF set with a variance determined by the PDF uncertainty given by the eigenvectors. Both reweighting methods are imple- 776 6 Alternatives to DGLAP Formalism mented in HERAFitter.

obtained from the ensemble as

$$\langle \mathcal{O}(\{f\}) \rangle = \frac{1}{N_{\text{rep}}} \sum_{k=1}^{N_{\text{rep}}} \mathcal{O}(f^k),$$
 (23)

and the uncertainty as the standard deviation of the sample. 787 6.1 Dipole Models

Upon inclusion of new data the prior probability distri-

$$w_k = \frac{(\chi_k^2)^{\frac{1}{2}(N_{\text{data}} - 1)} e^{-\frac{1}{2}\chi_k^2}}{\frac{1}{N_{\text{rep}}} \sum_{k=1}^{N_{\text{rep}}} (\chi_k^2)^{\frac{1}{2}(N_{\text{data}} - 1)} e^{-\frac{1}{2}\chi_k^2}},$$
(24)

specific replica for which the weight is calculated and χ_k^2 is 796 are embedded in the dipole scattering amplitude. the chi-square of the new data obtained using the k-th PDF 797

of new data, the prediction for a given observable can be computed as the weighted average,

$$\langle \mathcal{O}(\{f\}) \rangle = \frac{1}{N_{\text{rep}}} \sum_{k=1}^{N_{\text{rep}}} w_k \mathcal{O}(f^k).$$
 (25)

To simplify the use of reweighted set, an unweighted set (i.e. a set of equiprobable replicas which incorporates the information of the original weights) is generated according to the unweighting procedure described in [95]. In this respect, it is useful to recall that the number of effective replicas of a reweighted set is measured by its Shannon Entropy [96]

$$N_{\text{eff}} \equiv \exp\left\{\frac{1}{N_{\text{rep}}} \sum_{k=1}^{N_{\text{rep}}} w_k \ln(N_{\text{rep}}/w_k)\right\},\,\,(26)$$

PDFs. Bayesian Reweighting was first proposed for the PDF 769 cas set containing the same amount of information. As such, sets delivered in form of MC replicas ensembles by [90] and 770 the number of effective replicas, $N_{\rm eff}$, gives an indicative further developed by the NNPDF Collaboration [95, 96]. 771 measure of the optimal size of an unweighted replica set More recently, a method to preform Bayesian Reweighting 772 produced using the reweighting/unweighting procedure. No studies starting from PDF fits where uncertainties are pro- 773 extra information is gained by producing a final unweighted vided in form of parameter eigenvectors has been also de- 774 set that has a number of replicas (significantly) larger than

The Bayesian Reweighting technique relies on the fact 777 The QCD calculations based on the DGLAP [21-25] evothat the MC replicas of a PDF sets (i.e. NNPDF) give a 778 lution equations are very successful in describing all relerepresentation of the probability distribution in the space 779 vant hard scattering data in the perturbative region $Q^2 \gtrsim$ of PDFs. In particular, the PDFs are represented as ensem- 780 1 GeV 2 . bution, given by the prior PDF set, is updated according to 788 The dipole picture provides an alternative approach to the Bayes Theorem and the weight of each replica, w_k , is up- 789 proton-virtual photon scattering at low x providing the de-790 scription of both inclusive and diffractive processes. In this ⁷⁹¹ approach, the virtual photon fluctuates into a $q\bar{q}$ (or $q\bar{q}g$) (24) 792 dipole which interacts with the proton [97]. The dipoles can 793 be considered as quasi-stable quantum mechanical states, which have very long life time $\propto 1/m_p x$ and a size which is where N_{data} is the number of new data points, k denotes the 795 not changed by scattering. The dynamics of the interaction

Several dipole models which assume different behaviour replica. Given a PDF set and a corresponding set of weights, 798 of the dipole-proton cross sections are implemented in HERAFitter: which describes the impact on the same set of the inclusion 799 the Golec-Biernat-Wüsthoff (GBW) dipole saturation model [32],

the colour glass condensate approach to the high parton density regime called the Iancu-Itakura-Munier (IIM) dipole model [33#] the DIS cross section can be written as a convolution in and a modified GBW model which takes into account the effects of DGLAP evolution called the Bartels-Golec-Kowalski (BGK) dipole model [34].

GBW model: In the GBW model the dipole-proton cross section $\sigma_{\rm dip}$ is given by

$$\sigma_{\text{dip}}(x, r^2) = \sigma_0 \left(1 - \exp\left[-\frac{r^2}{4R_0^2(x)} \right] \right), \tag{27}$$

the quark and the antiquark, and R_0^2 is an x-dependent scale bining the resummation of small-x logarithmic contributions parameter which represents the spacing of the gluons in the 846 [115-117] with medium-x and large-x contributions to parproton. $R_0^2(x) = (x/x_0)^{\lambda} 1/\text{GeV}^2$ is called the saturation ra- 847 ton splitting [21, 24, 25] according to the CCFM evolution dius. The cross-section normalisation σ_0 , x_0 , and λ are pa- 848 equation [29, 118, 119]. rameters of the model commonly fitted to the DIS data. This 849 model gives exact Bjorken scaling when the dipole size r is 850 logarithmically enhanced small-x contributions to all orders

sion for the dipole cross section which is based on the Balitsky⁸⁵⁴ torisation scheme [120, 121]. Kovchegov equation [98]. The explicit formula for $\sigma_{\rm dip}$ can 855 be found in [33]. The alternative scale parameter \tilde{R} , x_0 and 856 λ are fitted parameters of the model.

BGK model: The BGK model is a modification of the GBW 859 model assuming that the spacing R_0 is inverse of the gluon 860 density and taking into account the DGLAP evolution of the latter. The gluon density parametrised at some starting scale 861 CCFM Grid Techniques: The CCFM evolution cannot be by Eq. 14 is evolved to larger scales using DGLAP evolu- 862 written easily in an analytic closed form. For this reason a tion. 823

BGK model with valence quarks: The dipole models are 865 valid in the low-x region only, where the valence quark conin HERAFitter the contribution of the valence quarks can be taken into account in the original BGK model [100].

6.2 Transverse Momentum Dependent PDFs

QCD calculations of multiple-scale processes and complex 871 tor gluon and p is the evolution variable. final-states require in general transverse-momentum depen- 872 dent (TMD) [13], or unintegrated, parton distribution and 873 evolution. It is defined on a grid of $50 \otimes 50 \otimes 50$ bins in parton decay functions [101–109]. The TMD factorisation 874 x, k_t, p . The binning in the grid is logarithmic, except for the has been proven recently [13] for inclusive DIS. For partic- 875 longitudinal variable x where 40 bins in logarithmic spacing ular hadron-hadron scattering processes, like heavy flavor, 876 below 0.1, and 10 bins in linear spacing above 0.1 are used. vector boson and Higgs production, TMD factorisation has 877 112].

In the framework of high-energy factorisation [110, 113, both longitudinal and transverse momenta of the TMD parton density function $\mathcal{A}(x, k_t, \mu)$ with the off-shell partonic matrix elements, as follows

$$\sigma_j(x,Q^2) = \int_x^1 dz \int d^2k_t \ \hat{\sigma}_j(x,Q^2,z,k_t) \ \mathscr{A}\left(z,k_t,\mu_F^2\right) \tag{28}$$

with the DIS cross sections σ_j , (j=2,L) related to the struc-(27) 842 ture functions F_2 and F_L . The hard-scattering kernels $\hat{\sigma}_j$ of Eq. 28, are k_t -dependent and the evolution of the transversewhere r corresponds to the transverse separation between 844 momentum dependent gluon density $\mathscr A$ is obtained by com-

The factorisation formula (28) allows resummation of 851 in perturbation theory, both in the hard scattering coeffi-852 cients and in the parton evolution, fully taking into account IIM model: The IIM model assumes an improved expres- 853 the dependence on the factorisation scale μ_F and on the fac-

> The cross section σ_i , (j = 2, L) is calculated in a FFN scheme, where only the boson-gluon fusion process ($\gamma^* g^* \rightarrow$ $q\bar{q}$) is included. The masses of the quarks are explicitly included as parameters of the model. In addition to $\gamma^* g^* \to q\bar{q}$, the contribution from valence quarks is included via $\gamma^* q \rightarrow q$ by using a CCFM evolution of valence quarks [122, 123].

863 Monte Carlo method is employed, which is however timeconsuming, and cannot be used in a straightforward manner in a fit program.

Following the convolution method introduced in [123, tribution to the total proton momentum is 5% to 15% for $_{867}$ 124], the kernel $\tilde{\mathscr{A}}(x'', k_t, p)$ is determined from the Monte x from 0.0001 to 0.01 [99]. The new HERA F₂ measure- 868 Carlo solution of the CCFM evolution equation, and then ments have a precision which is better than 2%. Therefore, see folded with the non-perturbative starting distribution $\mathcal{A}_0(x)$

$$x\mathscr{A}(x,k_t,p) = x \int dx' \int dx'' \mathscr{A}_0(x') \widetilde{\mathscr{A}}(x'',k_t,p) \,\delta(x'x''-x)$$
$$= \int dx' \mathscr{A}_0(x') \cdot \frac{x}{x'} \,\widetilde{\mathscr{A}}\left(\frac{x}{x'},k_t,p\right), \tag{29}$$

where k_t denotes the transverse momentum of the propaga-

The kernel $\tilde{\mathscr{A}}$ incorporates all of the dynamics of the

Calculation of the cross section according to Eq. 28 inalso been proven in the high-energy (small-x) limit [110-878 volves a multidimensional Monte Carlo integration which 879 is time consuming and suffers from numerical fluctuations.

ing the calculation of numerical derivatives in the search for 921 each kinematic bin of the measurement, pulls are provided the minimum. Instead the following equation is applied:

$$\sigma(x, Q^2) = \int_x^1 dx_g \mathscr{A}(x_g, k_t, p) \hat{\sigma}(x, x_g, Q^2),$$

$$= \int_x^1 dx' \mathscr{A}_0(x') \cdot \tilde{\sigma}(x/x', Q^2),$$
 (30)

where first $\tilde{\sigma}(x', Q^2)$ is calculated numerically with a Monte Carlo integration on a grid in x for the values of Q^2 used in the fit. Then the last step in Eq. 30 is performed with a fast numerical gauss integration, which can be used in standard fit procedures.

Functional Forms for TMD parametrisation: For the starting distribution \mathcal{A}_0 , at the starting scale Q_0^2 , the following form is used:

$$x \mathcal{A}_0(x, k_t) = Nx^{-B} (1 - x)^C (1 - Dx + E\sqrt{x}) \exp[-k_t^2/\sigma^2], 1$$

with $\sigma^2 = Q_0^2/2$ and the free parameters N, B, C, D, E. Valence quarks are treated using the method of Ref. [122] as described in Ref. [123] with a starting distribution taken from any collinear PDF and imposing the flavor sum rule at every scale p.

The TMD parton densities can be plotted either with HERAFitter

provided tools or with TMDplotter [39].

7 HERAFitter Code Organisation

HERAFitter is an open source code and it can be downloaded from the dedicated webpage [1] together with its supporting documentation and fast grid theory files (described in section 4) associated with the properly formatted data files. The source code contains all the relevant information to perform QCD fits with HERA DIS data as a default set 1. The performance time depends on the fitting options and varies from 10 minutes (using "FAST" techniques as described in section 4) to several hours when full uncertainties are estimated. The HERAFitter code is a combination of C++ and Fortran 77 libraries with minimal dependencies, i.e. for the default fitting options no external dependencies are required except QCDNUM evolution program [26] and CERN libraries. The ROOT libraries are only required for the drawing tools and when invoking APPLGRID. Drawing tool inbuilt in HERAFitter provides a qualitative and quantitative assessment of the results. Fig. 8 shows an illustration of a comparison between the inclusive NC data from the HERA I with the predictions based on HERAPDF1.0 PDFs. The consistency of the measurements and the theory is expressed by pulls, defined as a difference between data

This cannot be employed directly in a fit procedure involv- 920 and theory divided by the uncorrelated error of the data. In in units of standard deviation (sigma).

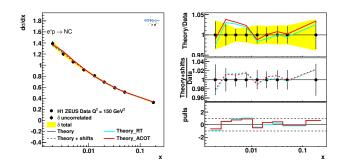

Fig. 8 An illustration of the consistency of HERA measurements [40] and the theory predictions, obtained in HERAFitter with the default drawing tool.

In HERAFitter there are also available cache options, fast evolution kernels, and the OpenMP (Open Multi-Processing) interface which allows parallel applications of the GM-VFNS theory predictions in DIS. In addition, the HERAFitter references and GNU public licence are provided together with

929 8 Applications of HERAFitter

930 The HERAFitter program was used in a number of exper-931 imental and theoretical analyses. This list includes several LHC analyses of SM processes, namely inclusive Drell-Yan and Wand Z production [86, 125–128], inclusive jet production [129]. The results of QCD analyses using HERAFitter 935 were also published by HERA experiments in the inclusive 936 [40, 130] and the heavy flavour production measurements 937 [131, 132]. Following theory and phenomenology studies were performed with HERAFitter: a determination of the 939 transverse momentum dependent gluon density using pre-940 cision HERA data [123], an analysis of HERA data within a dipole model [100], the study of the low-x uncertainties 942 in PDFs determined from the HERA data using different parametrisations [87] and the impact of QED radiative corrections on PDFs [133]. A recent study based on a set of PDFs determined with the HERAFitter and addressing the correlated uncertainties between orders was published in [94]

The HERAFitter framework has been used to produce PDF grids from the QCD analyses performed at HERA [40, 134] and at the LHC [135], using measurements from AT-950 LAS [86, 129], which can be used to study predictions for SM or beyond SM processes. Moreover, HERAFitter pro-952 vides a possibility to perform various benchmarking exer-953 cises [136] and impact studies for possible future colliders as demonstrated by the QCD studies at the LHeC [137].

¹Default settings in HERAFitter are tuned to reproduce the central HERAPDF1.0 set.

9 Summary

6 HERAFitter is an open-source platform designed to study 1007
7 the structure of the proton. It provides unique and flexible 1008
8 framework with a wide variety of QCD tools to facilitate 1009
9 analyses of the experimental data and theoretical calcula-1010
10 tions. HERAFitter allows for direct comparisons of vari-1011
11 ous theoretical approaches under the same settings, differ-1012
2 ent methodologies in treating the experimental and model 1013
3 uncertainties and can be used for benchmarking studies. The 1014
4 growth of HERAFitter is driven by the latest QCD advances 1015
5 in theoretical calculations and in precision of experimental 1016
6 data.

Acknowledgements HERAFitter developers team acknowledges the 1019
kind hospitality of DESY and funding by the Helmholtz Alliance "Physicso
at the Terascale" of the Helmholtz Association. We are grateful to the 1021
DESY IT department for their support of the HERAFitter developers. Additional support was received from the BMBF-JINR cooperation program, the Heisenberg-Landau program, the RFBR grant 12-02-1023
91526-CERN a, the Polish NSC project DEC-2011/03/B/ST2/00220 1024
and a dedicated funding of the Initiative and Networking Fond of Helmholtz
Association SO-072. We also acknowledge Nathan Hartland with Luigi
Del Debbio for contributing to the implementation of the Bayesian
Reweighting technique and would like to thank R. Thorne for fruitful 1027
discussions.
