Abstract HERAFitter [1] is an open-source package which provides a framework for the determination of the parton distribution functions (PDFs) of the proton and for multifold analyses in Quantum Chromodynamics (QCD).

Measurements of lepton-proton deep inelastic scattering (DIS) and of proton-proton (proton-antiproton) collisions at hadron colliders are included in the HERAFitter package, and are used to probe and constrain the partonic content of the proton.

The partonic distributions are determined by using the 60 sections are written as factorisation properties of the hadronic cross sections in which short-distance perturbatively calculable partonic scattering cross sections and long-distance contributions that are the non-perturbative universal PDFs, are factorised.

The HERAFitter platform provides a broad choice of options for the treatment of the experimental uncertainties and a common environment where a large number of theoretical calculations and methodological options are used to perform detailed QCD analyses. The general structure of HERAFitter together with available methods are described in this paper.

## 1 Introduction

The constant inflow of new experimental measurements with 97 tering processes of the experimental measurement. It is deunprecedented accuracy from hadron colliders is a remark- 98 veloped for determination of PDFs and extraction of funable challenge for the high energy physics community to 99 damental QCD parameters such as the heavy quark masses provide higher-order theory predictions and to develop effi- 100 and the strong coupling constant. This platform also procient tools and methods for data analysis. The recent discov- 101 vides the basis for comparisons of different theoretical apery of the Higgs boson [2, 3] and the extensive searches for 102 proaches and can be used for direct tests of the impact of signals of new physics in LHC proton-proton collisions de- 103 new experimental data on the SM parameters in the QCD mand high-precision computations to test the validity of the 104 analyses. Standard Model (SM) and factorisation in Quantum Chro- 105 modynamics (QCD). According to the collinear factorisa- 106 overview of HERAFitter are presented in section 2. Sec-

$$\sigma(\alpha_{s}(\mu_{R}), \mu_{R}, \mu_{F}) = \sum_{a,b} \int_{0}^{1} dx_{1} dx_{2} \times f_{a}(x_{1}, \alpha_{s}(\mu_{R}), \mu_{F}) f_{b}(x_{2}, \alpha_{s}(\mu_{R}), \mu_{F}) \times \hat{\sigma}^{ab}(x_{1}, x_{2}; \alpha_{s}(\mu_{R}), \mu_{R}, \mu_{F})$$
(1)

where the cross section  $\sigma$  for any hard-scattering inclusive process is expressed as a convolution of Parton Distribution Functions (PDFs)  $f_a$  and  $f_b$  with the partonic cross section  $\hat{\sigma}^{ab}$ . At Leading-Order (LO), the PDFs represent the probability of finding a specific parton a(b) in the first (second) proton carrying a fraction  $x_1$  ( $x_2$ ) of its momentum. Indices a and b in the Eq. 1 indicate the various kinds of partons, i.e. 68 gluons, quarks and antiquarks of different flavours, that are 69 considered as the constituents of the proton. The PDFs and the partonic cross sections depend on the strong coupling  $\alpha_{\rm s}$ , and the factorisation and renormalisation scales,  $\mu_{\rm F}$  and  $\mu_{\rm R}$ , respectively. The partonic cross sections  $\hat{\sigma}^{ab}$  are calculated in pQCD whereas PDFs are constrained by global fits 74 to variety of the hard-process experimental data employing universality of PDFs within a particular factorisation scheme 76 **[4, 5]**.

Measurements of the inclusive Neutral Current (NC) and 78 Charged Current (CC) Deep Inelastic Scattering (DIS) at the <sup>79</sup> ep collider HERA provide crucial information for determin-80 ing the PDFs. The gluon density in small and medium x81 can be accurately determined solely from the HERA data. Many processes in pp and  $p\bar{p}$  collisions at LHC and Teva-83 tron, respectively, probe PDFs in the kinematic ranges, complementary to the DIS measurements. Therefore inclusion of the LHC and Tevatron data in the QCD analysis of the proton structure provide additional constraints on the PDFs, 87 improving either their precision, or providing valuable in-88 formation on the correlations of PDFs with the fundamen-89 tal QCD parameters like the strong coupling or the quark 90 masses. In this context, the processes of interest at hadron olliders are Drell-Yan (DY) production, W-boson asymme- $_{92}$  tries, associated production of W or Z bosons and heavy quarks, top quark, jet and prompt photon production.

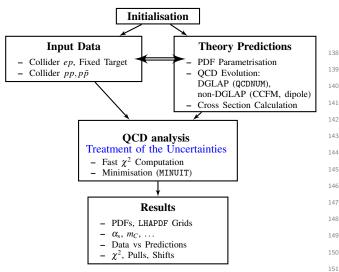

This paper describes the open-source QCD fit platform 95 HERAFitter which includes the set of tools essential for a <sub>96</sub> comprehensive global QCD analysis of pp,  $p\bar{p}$  and ep scat-

This paper is organised as follows. The structure and tion in perturbative QCD (pQCD) hadronic inclusive cross 107 tion 3 discusses the various processes and corresponding theoretical calculations performed in the collinear factorisation using the DGLAP [6–10] formalism, available in HERAFitter. Section 4 presents various fast techniques employed by the theory calculations used in HERAFitter. Section 5 elucidates the methodology of determining PDFs through fits based on various  $\chi^2$  definitions used in the minimisation procedure. Alternative approaches to the DGLAP formalism are presented in section 6. Specific applications of the package are given in section 8 and the summary is presented in section 9.

## 2 The HERAFitter Structure

HERAFitter is a flexible open-source platform for the QCD analyses of different experimental measurements, providing a versatile environment for benchmarking studies. It is widely used within the LHC experiments [11–16].

The functionality of HERAFitter is schematically illustrated in Fig. 1 and it can be divided into four main blocks:

Input data: Different available measurements from vari- 155 ous processes are implemented in the HERAFitter pack- 156 age including the full information on their uncorrelated and correlated uncertainties. HERA data are sensitive to 158 light quark and gluon densities mostly through scaling 159 violations, covering low and medium x ranges. These 160 data are the basis of any proton PDF extraction, and 161 are used by all global PDF groups [17-21]. However, 162 improvements in precision of PDFs require additional 163 constraints on the gluon and quark distributions at high- 164 x, better understanding of heavy quark distributions and 165 decomposition of the light-quark sea. For these purposes, 166

Data	Process	Reaction	Theory calculations, schemes

the measurements of the fixed-target experiments, Tevatron and LHC are of particular importance. The processes that are currently available in HERAFitter framework are listed in Tab. 1.

**Theory predictions:** Predictions for cross section of different processes are obtained using the factorisation approach (Eq. 1). The PDFs are parametrised at a starting input scale  $Q_0^2$  by a chosen functional form with a set of free parameters p. These PDFs are evolved to the scale of the measurement  $Q^2$ ,  $Q^2 > Q_0^2$ . The evolution follows either DGLAP [6-10] (as implemented in QCDNUM [22]), CCFM [23–26] (as implemented in uPDFevolv [27]). The prediction of a particular process cross section is obtained by a convolution of the evolved PDFs and the partonic cross section, calculated at a certain order in OCD with a appropriate theory calculation (as listed in Tab. 1). Alternatively, predictions using dipole models [28–30] can be also obtained.

QCD analysis: The PDFs are determined by the least square fit, minimising the  $\chi^2$  function, formed using the input data and theory predictions, with the MINUIT [31] program. Various choices of accounting for the experimental uncertainties are employed in HERAFitter, either using a nuisance parameter method for the correlated systematic uncertainties, or a covariance matrix method as described in section 5.2). In addition, HERAFitter allows to study different statistics assumptions for the distributions of the systematic uncertainties, like Gauss, LogNormal [32] (see section 5.3).

**Results:** The resulting PDFs are provided in a format ready to be used by the LHAPDF library [33, 34] (or by TMDlib [35]). HERAFitter drawing tools can be used to display the PDFs with their uncertainties at a chosen scale. As an example, a first set of PDFs extracted using HERAFitter from HERA I data, HERAPDF1.0 [36], is shown in Fig. 2. The comparison of data used in the fit to the theory predictions are also produced. The inclusive NC data from

**Fig. 2** Distributions of valence  $(xu_v, xd_v)$ , sea (xS) and the gluon (g)densities in HERAPDF1.0 [36]. The gluon and the sea distributions are scaled down by a factor of 20. The experimental, model and parametrisation uncertainties are shown as colored bands.

the HERA I are compared with the predictions based on HERAPDF1.0 PDFs in Fig. 3. Also shown are theory predictions, obtained using the nuisance parameter method, which accounts for correlated systematic shifts when using the nuisance parameter method that accounts for correlated systematic uncertainties (see section 5.2). The consistency of the measurements and the theory is expressed by pulls, defined as a difference between data and theory divided by the uncorrelated error of the data. In each kinematic bin of the measurement, pulls are provided in units of standard deviation (sigma).

# 3 Theoretical Input

cesses available in HERAFitter is described.

## 3.1 Deep Inelastic Scattering and Proton Structure

DIS data provide the backbone of any PDF fit. The forma-191 lism that relates the DIS measurements to pQCD and the

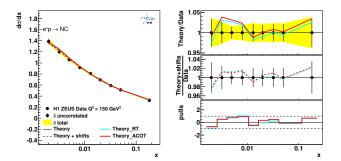

Fig. 3 An illustration of the consistency of HERA measurements [36] and the theory predictions, obtained in HERAFitter with the default drawing tool.

192 PDFs has been described in detail in many extensive reviews (see e.g. [37]) and it is only briefly summarised here. DIS is the process where a lepton scatters off the constituents of the proton by a virtual exchange of a NC or CC vector boson and, as a result, a scattered lepton and a multi-hadronic final state are produced. The common DIS kinematic variables are the absolute squared four-momentum of the exchange boson,  $Q^2$ , the Bjorken x, and the inelasticity y, related by  $y = Q^2/sx$ , where s is the squared centre-of-mass (c.o.m.)

202 The NC cross section can be expressed in terms of gener-203 alised structure functions:

$$\frac{d^2 \sigma_{NC}^{e^{\pm} p}}{dx dQ^2} = \frac{2\pi \alpha^2}{x Q^4} \cdot \sigma_{r,NC}^{e^{\pm} p},\tag{2}$$

$$\sigma_{r,NC}^{e^{\pm}p} = Y_{+}\tilde{F}_{2}^{\pm} \mp Y_{-}x\tilde{F}_{3}^{\pm} - y^{2}\tilde{F}_{L}^{\pm}, \tag{3}$$

where the electromagnetic coupling constant  $\alpha$ , the photon propagator and a helicity factor are absorbed in the definition of reduced cross section  $\sigma_r$ , and  $Y_{\pm} = 1 \pm (1 - y)^2$ (additional terms of  $O(1/Q^2)$  are numerically small at the HERA kinematics and are neglected). The generalised structure functions  $\tilde{F}_{2,3}$  can be written as linear combinations of the proton structure functions  $F_2^{\gamma}, F_{2,3}^{\gamma Z}$  and  $F_{2,3}^{Z}$  associated to pure photon exchange terms, photon-Z interference terms and pure Z exchange terms, respectively. The structure function  $\tilde{F}_2$  is the dominant contribution to the cross section,  $x\tilde{F}_3$ becomes important at high  $Q^2$  and  $\tilde{F}_L$  is sizable only at high

The inclusive CC ep cross section, analogous to the NC 217 case, can be expressed in terms of another set of structure functions and in LO in  $\alpha_s$ , the  $e^+p$  and  $e^-p$  cross sections In this section the theoretical formalism for various pro- 219 are sensitive to different combinations of the quark flavour 220 densities:

$$\frac{d^2 \sigma_{CC}^{e^{\pm} p}}{dx dQ^2} = \frac{1 \pm P}{2} \frac{G_F^2}{2\pi x} \left[ \frac{M_W^2}{M_W^2 + Q^2} \right] \cdot \sigma_{r,CC}^{e^{\pm} p} \tag{4}$$

$$\sigma_{r,CC}^{e^+p} \approx x[\overline{u} + \overline{c}] + (1 - y)^2 x[d + s], \tag{5}$$

$$\sigma_{r,CC}^{e^{-p}} \approx x[u+c] + (1-y)^2 x[\overline{d} + \overline{s}], \tag{6}$$

where P represents the lepton beam polarisation. The QCD  $_{274}$  predictions for the DIS structure functions are obtained by  $_{275}$  convoluting the PDFs with the respective coefficient func- $_{276}$  tions

The DIS measurements span a large range of  $Q^2$  from 278 few GeV<sup>2</sup> to about  $10^5$  GeV<sup>2</sup>, crossing heavy-quark mass 279 thresholds, thus the treatment of heavy quarks (charm and 280 beauty) and of their masses becomes important. There are 281 different approaches to the treatment of heavy quark production that should be equivalent if calculations are carried 283 out to all orders in  $\alpha_s$ . Several variants of these schemes are 284 implemented in HERAFitter and they are briefly discussed 285 below

#### Zero-Mass Variable Flavour Number (ZM-VFN)[38]:

In this scheme, the heavy quark densities appear in the proton at  $Q^2$  values above  $\sim m_h^2$  (heavy quark mass) and the heavy quarks are treated as massless in both the initial and final states of the hard scattering process. The lowest order process is the scattering of lepton off the heavy quark via boson exchange. This scheme is expected to be reliable only in the region with  $Q^2 \gg m_h^2$ . In HERAFitter this scheme is available for the DIS structure function calculation via the interface to the QCDNUM convolution engine.

299

## Fixed Flavour Number (FFN)[39–41]:

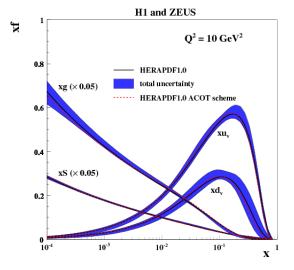

In this scheme only the gluon and the light quarks are 300 considered as partons within the proton and massive quark<sup>391</sup> are produced perturbatively in the final state. The low- 302 est order process is the heavy quark-antiquark pair pro- 303 duction in the boson-gluon fusion. In HERAFitter this scheme can be accessed via the QCDNUM implementation or through the interface to the open-source code OPENQCDRAD [42], as implemented by the ABM group. Through QCDNUM, the calculation of the heavy quark contributions to DIS structure functions are available at Nextto-Leading-Order (NLO), at  $O(\alpha_s^2)$ , and only electromagnetic exchange contributions are taken into account. Through the ABM implementation the heavy quark contributions to CC structure functions are available and, for the NC case, the QCD corrections to the coefficient functions at Next-to-Next-to Leading Order (NNLO) are provided at the best currently known approximation [43]. The ABM implementation also includes the definition in  $\overline{MS}$  scheme with the running heavy-quark mass [44]. The scheme has the advantage of reducing the sensitivity of the DIS cross sections to higher order corrections, and improving the theoretical precision of the mass definition.

## **General-Mass Variable Flavour Number (GM-VFN)[45]:**

It this scheme, heavy quark production is treated for  $Q^2 \le m_h^2$  in the FFN scheme and for  $Q^2 \gg m_h^2$  in a masless scheme. The recent series of PDF groups that use this

scheme are MSTW, CT(CTEQ), NNPDF, and HERA-PDF. HERAFitter implements different variants of the GM-VFN scheme and they are presented below:

- GM-VFN Thorne-Roberts scheme: The Thorne-Roberts (TR) scheme [46] was designed to provide a smooth transition from the massive FFN scheme at low scales  $Q^2 < m_h^2$  to the massless ZM-VFNS scheme at high scales  $Q^2 \gg m_h^2$ . However, the original version was technically difficult to implement beyond NLO, and was updated to the TR' scheme [47]. There are two different variants of the TR' schemes: TR' standard (as used in MSTW PDF sets [17, 47]) and TR' optimal [48], with a smoother transition across the heavy quark threshold region. Both variants are accessible within the HERAFitter package at LO, NLO and NNLO.
- **GM-VFN ACOT scheme:** The Aivazis-Collins-Olness-Tung (ACOT) scheme belongs to the group of VFN factorisation schemes that use the renormalisation method of Collins-Wilczek-Zee (CWZ) [49]. This scheme unifies the low scale  $Q^2 < m_h^2$  and high scale  $Q^2 > m_h^2$  regions with a smooth interpolation across the full energy range. Within the ACOTpackage, different variants of the ACOT scheme are available: ACOT-Full [50], S-ACOT- $\chi$  [51, 52], ACOT-ZM [50],  $\overline{\text{MS}}$  at LO and NLO. For the longitudinal structure function higher order calculations are also available. A compasion of PDFs extracted from the QCD fits to the HERA data with the TR' and ACOT-Full schemes is illustrated in Fig. 4.

**Fig. 4** Overview showing the u- and d-valence, the total sea (scaled), and gluon (scaled) PDFs of the NLO HERAPDF1.0 set [36] with their total uncertainty at the scale of  $Q^2 = 10 \text{ GeV}^2$  obtained using the TR' scheme and compared to the PDFs obtained with the ACOT scheme using the k-factor technique (red).

#### 3.2 Electroweak Corrections to DIS

Calculations of higher-order electroweak corrections to DIS scattering at HERA are available in HERAFitter in the onshell scheme. In this scheme the gauge bosons masses  $M_W$ and  $M_Z$  are treated symmetrically as basic parameters together with the top, Higgs and fermion masses. These electroweak corrections are based on the EPRCpackage [53]. The  $f_a^{IR}$  are obtained from a fit to the data. code provides the running of electromagnetic coupling  $\alpha$  using the most recent parametrisation of the hadronic contribution to  $\Delta_{\alpha}$  [54], as well as an older version from Burkhard

## 3.3 Diffractive PDFs

hadronic final state by a large rapidity gap. This is inter- 351 Sity [58]. preted as the dissociation of the virtual photon into hadronic system X with the invariant mass much smaller than the photon-proton c.o.m. energy  $W = ys - Q^2 + m_p^2(1-y)$ , where  $m_p$  is proton's mass, and the same net quantum numbers as the exchanged photon. For such a processes, the diffractive DIS is mediated by the exchange of a hard Pomeron or a secondary Reggeon with the vacuum quantum numbers. The factorisable pomeron picture has proved remarkably successful in the description of most of these data.

The kinematic variables squared four-momentum transfer t (the undetected momentum transfer to the proton system) and the mass  $M_X$  of the diffractively produced final state appear for the diffrative process in addition to the usual DIS variables x,  $Q^2$ . In practice, the variable  $M_X$  is often replaced by dimensionless quantity  $\beta = \frac{Q^2}{M_X^2 + Q^2 - t}$ . In models based on a factorisable pomeron,  $\beta$  may be viewed at LO as the fraction of the pomeron longitudinal momentum which is carried by the struck parton,  $x = \beta x_{IP}$ .

For the inclusive case, the diffractive cross-section reads as:

$$\frac{d\sigma}{d\beta dQ^2 dx_{IP} dt} = \frac{2\pi\alpha^2}{\beta Q^4} \left( 1 + (1 - y)^2 \right) \overline{\sigma}^{D(4)}(\beta, Q^2, x_{IP}, t) \tag{7}$$

with the "reduced cross-section":

$$\overline{\sigma}^{D(4)} = F_2^{D(4)} - \frac{y^2}{1 + (1 - y)^2} F_L^{D(4)}.$$
 (8)

formula. In this way, the diffractive structure functions can 361 be expressed as convolutions of the calculable coefficient 362 functions, which in general depend on  $x_{IP}$ ,  $Q^2$ ,  $\beta$ , t.

The diffractive PDFs in HERAFitter [56, 57] are implemented as a sum of two factorised contributions:

$$\Phi_{IP}(x_{IP},t) f_a^{Pom}(\beta,Q^2) + \Phi_{IR}(x_{IP},t) f_a^{IR}(\beta,Q^2), \qquad (9)$$

where  $\Phi(x_{IP},t)$  are the Regge type fluxes. The Reggeon PDFs,

# 3.4 Drell-Yan Processes in pp or $p\bar{p}$ Collisions

341 Drell-Yan process provides further valuable information about PDFs. In pp and  $p\bar{p}$  scattering, the  $Z/\gamma^*$  and W production probe bi-linear combinations of quarks. Complementary in-344 formation on the different quark densities can be obtained Similarly to standard PDFs, diffractive parton distributions  $_{345}$  from the W asymmetry (d, u and their ratio), the ratio of (DPDFs) can be determined from QCD fits to diffractive 346 the W and Z cross sections (sensitive to the flavour compocross sections. About 10% of deep inelastic interactions at 347 sition of the quark sea, in particular to the s density), and HERA are diffractive, i.e. leading to events in which the 348 associated W and Z production with heavy quarks (sensiinteracting proton stays intact  $(ep \rightarrow eXp)$ . In the diffrac- 349 tive to s- and c-quark densities). Measurements at large botive process the proton is well separated from the rest of the  $_{350}$  son  $p_T \gtrsim M_{W,Z}$  are potentially sensitive to the gluon den-

> The LO DY for NC triple differential cross section in invariant mass M, boson rapidity v and lepton scattering angle  $\cos \theta$  in the parton c.o.m. frame can be written as [59, 60]:

$$\frac{d^3\sigma}{dMdyd\cos\theta} = \frac{\pi\alpha^2}{3MS} \sum_q P_q \left[ f_q(x_1, Q^2) f_{\bar{q}}(x_2, Q^2) + (q \leftrightarrow \bar{q}) \right], \tag{10}$$

where *S* is the squared c.o.m. beam energy,  $x_{1,2} = \frac{M}{\sqrt{S}} \exp(\pm y)$ ,  $f_q(x_1,Q^2)$  are the quark distribution functions, and  $P_q$  is a partonic cross section.

The LO expression for CC scattering has a form:

$$\frac{d^{3}\sigma}{dMdyd\cos\theta} = \frac{\pi\alpha^{2}}{48S\sin^{4}\theta_{W}} \frac{M^{3}(1-\cos\theta)^{2}}{(M^{2}-M_{W}^{2}) + \Gamma_{W}^{2}M_{W}^{2}}$$

$$\sum_{q_{1},q_{2}} V_{q_{1}q_{2}}^{2} f_{q_{1}}(x_{1},Q^{2}) f_{q_{2}}(x_{2},Q^{2}), \tag{11}$$

where  $V_{q_1q_2}$  is the Cabibbo-Kobayashi-Maskawa (CKM) quark mixing matrix and  $M_W$  and  $\Gamma_W$  are the W boson mass and decay width, respectively.

The simple form of these expressions allows the calculation of integrated cross sections without the use of Monte Carlo (MC) techniques which often introduce statistical fluc-(8) 358 tuations. In both NC and CC expressions the PDFs depend only on boson rapidity y and invariant mass M, while the in-Substituting  $x = x_{IP}\beta$  we can relate Eq. 7 to the standard DIS 360 tegral in  $\cos \theta$  can be solved analytically including the case of realistic kinematic cuts.

Currently, the predictions for W and  $Z/\gamma^*$  production functions with the diffractive quark and gluon distribution 363 are available to NNLO and W, Z in association with heavy 364 flavour quarks to NLO. There are several possibilities for HERAFitter.

### 3.5 Jet Production in ep and pp or $p\bar{p}$ Collisions

Cross section for production of the high-transverse-momentum hadronic jets is sensitive to the high-x gluon PDF (see e.g. [17]) therefore this process can be used to improve determination of the gluon PDF, which is particularly important for the Higgs production and searches for new physics. Jet production cross sections are currently only known to NLO, although calculations for higher-order contributions to jet production in proton-proton collisions are now quite advanced [ $\frac{66}{425}$ 68]. Within HERAFitter, the NLOJet++ program [69, 70] may be used for the calculations of jet production. Similarly to the DY case, the calculation is very demanding in terms of computing power. Therefore fast grid techniques are used to facilitate the QCD analyses including jet cross section measurements. in ep, pp and  $p\bar{p}$  collisions (for details see section 4).

## 3.6 Top-quark Production in pp or $p\bar{p}$ Collisions

Top-quark pairs  $(t\bar{t})$  are produced at hadron colliders dominantly via gg fusion (at the LHC) and  $q\bar{q}$  annihilation (at the Tevatron). Measurements of the  $t\bar{t}$  cross sections provide additional constraints in particular on the gluon density at medium to high values of x, on  $\alpha_s$  and on the topquark mass,  $m_t$  [71]. Precise predictions for the total  $t\bar{t}$  cross section are available to full NNLO [72]. They can be computed within HERAFitter via an interface to the program HATHOR [73]. Differential  $t\bar{t}$  cross section predictions can be used with MCFM [63, 74–77] at NLO accuracy interfaced to HERAFitter with fast grid techniques.

Single top quarks are produced via electroweak interactions and single-top cross sections can be used, for example, to probe the ratio of the u and d densities in the proton as well as the b-quark PDF. Predictions for single-top production are available only at NLO accuracy using MCFM.

## 4 Computational Techniques

equally good accuracy in order to maximise their impact in 454 cross sections and the fact that iterative PDF fitting pro-PDF fits. Perturbative calculations, however, get more and 455 cedures do not impose completely arbitrary change in the

obtaining the theoretical predictions for DY production in 410 Feynman diagrams. Nowadays even the most advanced perturbative techniques in combination with modern computing The NLO and NNLO calculations are computing power 412 hardware do not lead to sufficiently small turn-around times. calculation for arbitrary changes in input parameters is not necessary at each iteration step, two methods have been developed to resolve this problem: the techniques of k-factors and fast grids. Both are available in HERAFitter and described as follows.

# 4.1 *k*-factor Technique

The k-factors are defined as the ratio of the prediction of a higher-order (slow) pQCD calculation to a lower-order (fast) calculation. Because the k-factors depend on the phase space probed by the measurement, they have to be stored in a table 426 including dependence on the relevant kinematic variables. Before the start of a fitting procedure, the table of k-factors has to be computed once for a given PDF with the time consuming higher-order code. In subsequent iteration steps the theory prediction is derived from the fast lower-order calculation multiplied by the pre-tabulated *k*-factors.

This procedure, however, neglects the fact that the kfactors can be PDF dependent, as a consequence, they have 434 to be re-evaluated for the newly determined PDF at the end of the fit for the consistency check. Usually, the fit is repeated until input and output k-factors have converged. In summary, this technique avoids iteration of the higher-order calculation at each step, but still requires a couple of repetitions depending on the analysis.

An implementation of k-factor technique in HERAFitter 441 is used for the fast approximation of the time-consuming GM-VFN schemes for heavy quarks in DIS. 'FAST" heavyflavour schemes are implemented with k-factors defined as 444 the ratio of calculations at the same perturbative order but 445 for massive vs. massless quarks, e.g. NLO (massive)/NLO 446 (massless). These k-factors are calculated only for the starting PDF and hence, the "FAST" heavy flavour schemes should only be used for quick checks, i.e. full heavy flavour schemes are normally recommended. For the ACOT case, due to long computation time, the k-factors are used in the default settings in HERAFitter.

#### 4.2 Fast Grid Techniques

Precise measurements require theoretical predictions with 453 Fast grid techniques exploit the factorisable nature of the more involved with order due to an increasing number of 456 shape of the parameterised functions that represent each PDF.

497

502

504

506

507

508

509

Instead, it can be assumed that a generic PDF can be approx- 510 imated by a set of interpolating functions with a sufficient 511 number of support points. The accuracy of this approxima- 512 tion, can be checked and optimised in various ways with 513 the simplest one being an increase in the number of sup- 514 port points. Having ensured that the approximation bias is 515 negligibly small compared to the experimental and theoret-516 ical accuracy for all practical purposes, this method can be 517 used to perform the time consuming higher-order calcula- 518 tions (Eq. 1) only once for the set of interpolating functions. 519 Further iteration of a cross section evaluation for a particular 520 PDF set is fast and implies only sums over the set of inter- 521 polators multiplied by factors depending on the PDF. The 522 approach applies equally for the cross sections of processes 523 involving one or two hadrons in the initial state as well as to 524 their renormalisation and factorisation scale variation.

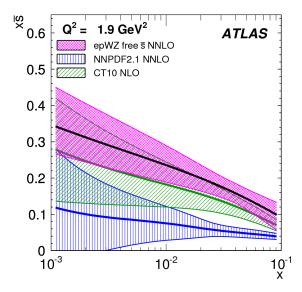

This technique was pioneered in the fastNLO project [78] 526 to facilitate the inclusion of notoriously time consuming jet 527 cross sections at NLO into PDF fits. The APPLGRID [79] 528 project developed an alternative method and, in addition to 529 jets, extended its applicability to other scattering processes, 530 such as DY, heavy quark pair production is association with 531 boson production, etc. While differing in their interpolation 532 and optimisation strategies, both packages construct tables 533 with grids for each bin of an observable in two steps: In the 534 first step, the accessible phase space in the parton momentum fractions x and the renormalisation and factorisation scales  $\mu_R$  and  $\mu_F$  is explored in order to optimize the table size. The second step consists of the actual grid filling for the requested observables. Higher-order cross sections can then be restored very efficiently from the pre-produced grids while varying externally provided PDF sets,  $\mu_R$  and  $\mu_F$ , or the strong coupling  $\alpha_s(\mu_R)$ . The approach can in principle be extended to arbitrary processes, but requires to establish an interface between the higher-order theory programs and the fast interpolation frameworks. Work in that direction is ongoing for both packages and described in more details in the following:

The fastNLO project [78] has been interfaced to the NLOJet++ program [69] for the calculation of jet production in DIS [80] as well as 2- and 3-jet production in hadron-hadron collisions at NLO [70, 81]. To demonstrate the applicability to higher-orders, threshold corrections at 2-loop order, which approximate the NNLO for the inclusive jet cross section, have been included into the framework as well [82] following Ref. [83]. The latest version of fastNLO convolution program [84] allows for a creation of tables where renormalisation and factorisation scales can be varied as a function of two pre-defined observables, e.g. jet transverse momentum p₁ and Q for DIS. The fastNLO code is available online and the jet cross-section grids computed for kinematics of various experiments can be downloaded as well [85].

Dedicated fastNLO libraries and tables with theory predictions for comparison to particular cross section measurements are included into the HERAFitter package. For the HERAFitter implementation, the evaluation of the strong coupling constant is taken consistently with the PDF evolution from the QCDNUM code.

- In the APPLGRID package [79, 86], in addition to the jet cross sections from NLOJet++ in  $pp(\bar{p})$  and DIS processes, the calculations of DY production are also implemented. The look-up tables (grids) can be generated with the customised versions of the MCFM parton level DY generator [61–63]. The variation of the renormalisation and factorisation scales is possible a posteriori, when calculating theory predictions with the APPLGRID tables, and independent variation of the strong coupling constant is also allowed. For NNLO predictions in HERAFitter, the k-factors technique can be also applied within the APPLGRID framework.

The HERAFitter interface to APPLGRID was in particular used by the ATLAS collaboration to extract the strange quark density of the proton from W and Z cross sections [11]. An illustration of ATLAS PDFs extracted employing these techniques is displayed in Fig. 5 together with the comparison to global PDF sets CT10 [18] and NNPDF2.1 [19].

**Fig. 5** The strange anti-quark density versus x for the ATLAS epWZ free sbar NNLO fit [11] (magenta band) compared to predictions from NNPDF2.1 (blue hatched) and CT10 (green hatched) at  $Q^2 = 1.9 \text{ GeV}^2$ . The ATLAS fit was performed using a k-factor approach for NNLO corrections.

## 535 5 Fit Methodology

556

557

558

559

561

565

568

569

Performing a QCD analysis one usually needs to check stability of the results w.r.t. different assumptions, e.g. the funcsitional parametrisation form, the heavy quarks mass values, 574 alternative theoretical calculations, method of minimisation, 575 interpretation of uncertainties, etc. It is also desirable to be 576 able to discriminate or quantify the effect of the chosen ansatz 577 ideally within a common framework, and HERAFitter is 578 optimally designed for such tests. The methodology employed 590 by HERAFitter relies on a flexible and modular framework 580 that allows for independent integration of the state-of-the-art techniques, either related to the inclusion of a new theoretical calculation, or of new approaches to treat uncertainties.

In this section we describe the available options in HERAFitter. In addition, as an alternative approach to a complete QCD fit, the Bayesian reweighting method, which is also available in HERAFitter, is described.

#### 5.1 Functional Forms for PDF Parametrisation

The PDFs are parametrised using several predefined functional form and different flavour decomposition. In HERAFitter, various functional forms to parametrise PDFs can be used:

588

**Standard Polynomials:** The standard polynomial form is 590 most commonly used by the PDF groups. A polynomial 591 functional form is used to parametrise the *x*-dependence 592 of the PDFs, where index *j* denotes each parametrised PDF:

$$xf_j(x) = A_j x^{B_j} (1 - x)^{C_j} P_i(x),$$
 (12)

The parametrised PDFs are the valence distributions  $xu_v$  and  $xd_v$ , the gluon distribution xg, and the u-type and d-type sea as constrained by HERA data alone,  $x\bar{U}$ ,  $x\bar{D}$ , where  $x\bar{U}=x\bar{u}$ ,  $x\bar{D}=x\bar{d}+x\bar{s}$  at the starting scale. The form of polynomials  $P_i(x)$  depdend on the style, defined as a steering parameter. The form  $(1+\varepsilon_j\sqrt{x}+D_jx+E_jx^2)$  is used for the HERAPDF [36] style with additional constraints relating to the flavour decomposition of the light sea. For the CTEQ style,  $P_i(x)$  takes the form  $e^{a_3x}(1+e^{a_4}x+e^{a_5}x^2)$  and, in contrast to polynomial form, is positive by constraction. QCD number and momentum sum rules are used to determine the normalisations A for the valence and gluon distributions, and the sum rule integrals are solved analytically.

**Bi-Log-Normal Distributions:** The parametrisation is motivated by multi-particle statistics and holds the following functional form:

$$xf_j(x) = a_j x^{p_j - b_j \log(x)} (1 - x)^{q_j - d_j \log(1 - x)}.$$
 (13)

This function can be regarded as a generalisation of the standard polynomial form described above, however, numerical integration of Eq. 13 is required in order to satisfy the QCD sum rules.

570

582

583

585

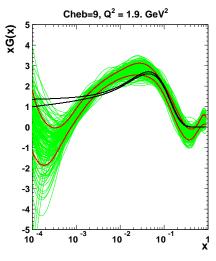

**Chebyshev Polynomials:** A flexible parameterization employed for the gluon and sea distributions and based on the Chebyshev polynomials. For better modeling the low-x asymptotic of those PDFs, the polynomial of the argument  $\log(x)$  are considered. Furthermore, the PDFs are multiplied by the factor of (1-x) to ensure that they vanish as  $x \to 1$ . The resulting parametric form reads

$$xg(x) = A_g(1-x) \sum_{i=0}^{N_g-1} A_{g_i} T_i \left( -\frac{2\log x - \log x_{\min}}{\log x_{\min}} \right),$$
 (14)

$$xS(x) = (1-x) \sum_{i=0}^{N_S - 1} A_{S_i} T_i \left( -\frac{2\log x - \log x_{\min}}{\log x_{\min}} \right),$$
 (15)

where  $T_i$  are the first-type Chebyshev polynomials of the order i. The normalisation factor  $A_g$  is defined from the momentum sum rule which can be evaluated analytically. The values of  $N_{g,S}$  up to 15 are allowed, however, already starting from  $N_{g,S} \ge 5$  the fit quality is already similar to the standard-polynomial parametrisation with a similar number of parameters.

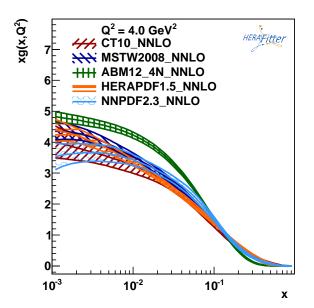

The low-x uncertainties in the PDFs determined from the HERA data using different parameterizations were studied in Ref. [87]. Figure 6 shows the comparison of the gluon density obtained with the parameterization Eq. 14,15 to the standard-polynomial one, for  $N_{g,S} = 9$ .

**Fig. 6** The gluon density is shown at the starting scale. The black lines correspond to the uncertainty band of the gluon distribution using a standard parameterisation and it is compared to the case of the Chebyshev parameterisation [87]. The uncertainty band for the latter case is estimated using the Monte Carlo technique with the green lines denoting fits to data replica. aRed lines indicate the standard deviation about the mean value of these replicas.

602

External PDFs: HERAFitter provides the possibility to 618 access external PDF sets, which can be used to compute 619 theoretical predictions for the various processes of interest as implemented in HERAFitter. This is possible via an interface to LHAPDF [33, 34] providing access to the global PDF sets. HERAFitter also allows to evolve 621 PDFs from LHAPDF with QCDNUM using the corresponding grids as a starting scale. Figure 7 illustrates the comparison of the PDFs accessed from LHAPDF as produced 624 with the drawing tools available in HERAFitter. 625

# 5.2 Representation of $\chi^2$

614

615

616

617

The PDF parameters are determined in HERAFitter by minimisation of the  $\chi^2$  function taking into account correlated and uncorrelated measurement uncertainties. There are various forms of  $\chi^2$  differing by method used to include the experimental uncertainties, e.g. using covariance matrix or providing nuisance parameters to encode dependence of each systematic source for each measurement data point, different scaling options, etc. The options available in HERAFitter are following.

Covariance Matrix Representation: For a data point  $\mu_i$  with a corresponding theory prediction  $m_i$ , the  $\chi^2$  function can be expressed in the following form:

$$\chi^{2}(m) = \sum_{i,k} (m_{i} - \mu_{i}) C_{ik}^{-1}(m_{k} - \mu_{k}), \tag{16}$$

where the experimental uncertainties are given in a form  $_{659}$  of covariance matrix  $C_{i,k}$  for measurements in bins i an  $_{660}$ 

k. The covariance matrix  $C_{ik}$  is given by the sum of statistical, uncorrelated and correlated systematic contributions:

$$C_{ik} = C_{ik}^{stat} + C_{ik}^{uncor} + C_{ik}^{sys}. (17)$$

With this representation the effect of a certain systematic source of the uncertainty cannot be distinguished from others.

Nuisance Parameters Representation: For the case when systematic uncertainties are separated by sources the  $\chi^2$  form is expressed as

$$\chi^{2}(m,b) = \sum_{i} \frac{\left[\mu_{i} - m_{i} \left(1 - \sum_{j} \gamma_{j}^{i} b_{j}\right)\right]^{2}}{\delta_{i,\text{unc}}^{2} m_{i}^{2} + \delta_{i,\text{stat}}^{2} \mu_{i} m_{i} \left(1 - \sum_{j} \gamma_{j}^{i} b_{j}\right)} + \sum_{j} b_{j}^{2}, \quad (18)$$

where,  $\delta_{i,\text{stat}}$  and  $\delta_{i,\text{unc}}$  are relative statistical and uncorrelated systematic uncertainties of the measurement i. Further,  $\gamma^i_j$  quantifies the sensitivity of the measurement to the correlated systematic source j. The function  $\chi^2$  depends in addition on the set of systematic nuisance parameters  $b_j$ . This definition of the  $\chi^2$  function assumes that systematic uncertainties are proportional to the central prediction values (multiplicative errors), whereas the statistical uncertainties scale with the square root of the expected number of events.

During the  $\chi^2$  minimisation, the nuisance parameters  $b_j$  and the PDFs are determined.

Mixed Form Representation: In some cases, the statistical and systematic uncertainties are provided in different forms. For example, the correlated experimental systematic uncertainties are available as nuisance parameters but the bin-to-bin statistical correlations are given in a form of covariance matrix. HERAFitter offers possibilities to include also the mixed form of treating statistical, uncorrelated and correlated systematic uncertainties.

Any source of the measurement systematic uncertainty can
be treated as additive or multiplicative. The statistical uncertainties can be included as additive or Poisson. Minimisation
with respect to nuisance parameters is performed analytically, however for more detailed studies of correlations individual nuisance parameters can be included in the MINUIT
minimisation.

### 5.3 Treatment of the Experimental Uncertainties

Three distinct methods for propagating experimental uncertainties to PDFs are implemented in HERAFitter and reviewed here: the Hessian, Offset, and Monte Carlo method.

**Hessian (Eigenvector) method:** The PDF uncertainties reflecting the uncertainties in experimental data are esitimated by examining the shape of  $\chi^2$  in the neighborhood

of the minimum [88]. Following approach of Ref. [88], the Hessian matrix is defined by the second derivatives of  $\chi^2$  on the fitted PDF parameters. The matrix is diagonalized and the Hessian eigenvectors are computed. Due to orthogonality, these vectors correspond to statistically independent sources of the uncertainties in the PDFs ob-

705

706

707

708

**Offset method:** The Offset method [89] uses also the  $\chi^2$ function for the central fit for which only uncorrelated uncertainties are taken into account. The goodness of the fit can no longer be judged from the  $\chi^2$  since correlated uncertainties are ignored. The correlated uncertainties are propagated into the PDF uncertainties performing the variants of fit with the experimental data varied by  $\pm 1\sigma$  from the central value for each systematic source. Since the resulting deviation of the PDF parameters from the ones obtained in the central fit are statistically independent, they are combined in quadrature to arive to the total PDF systematic uncertainty.

In most cases, the uncertainties estimated by the offset method are larger than those from the Hessian method.

Monte Carlo method: The Monte-Carlo technique [90, 91] can be used to determine PDF uncertainties. The uncertainties are estimated using the pseudo-data replicas (typically > 100) randomly generated from the measurement central values and their systematic and statistical uncertainties taking into account all point-to-point correlations. The QCD fit is performed for each replica and the PDF central values with their experimental uncertainties are estimated using distribution of the PDF parameters over these fits, i.e. the mean values and standard deviations over the replicas.

The MC method was checked against the standard error estimation of the PDF uncertainties obtained by the Hessian method. A good agreement was found between 709 5.4 Treatment of the Theoretical Input Parameters the methods once the Gaussian distribution of statistic sis [92].

to obtain correlated sets of PDFs at different perturbative 720 theory. order [94].

The nuisance parameter representation of  $\chi^2$  in Eq. 18 is 721 5.5 Bayesian Reweighting Techniques derived assuming symmetric experimental errors, however, the published systematic uncertainties are rather often asym- 722 As an alternative to performing a full QCD fit, HERAFitter

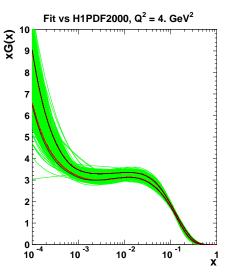

Fig. 8 Comparison between the standard error calculations as employed by the Hessian approach (black lines) and the MC approach (with more than 100 replicas) assuming Gaussian distribution for uncertainty distributions, shown here for each replica (green lines) together with the evaluated standard deviation (red lines) [32]. The black lines in the figure are mostly covered by the red lines.

on the assumption that asymmetric uncertainties can be described by a parabolic function and the nuisance parameter in Eq. 18 is modified as follows

$$\gamma_i^i \to \omega_i^i b_j + \gamma_i^i,$$
 (19)

where the coefficients  $\omega_i^i$ ,  $\gamma_i^i$  are defined by the up and down values of the systematic uncertainties,  $S_{ii}^{\pm}$ ,

$$\omega_{j}^{i} = \frac{1}{2} \left( S_{ij}^{+} + S_{ij}^{-} \right), \qquad \gamma_{j}^{i} = \frac{1}{2} \left( S_{ij}^{+} - S_{ij}^{-} \right).$$
 (20)

and systematic uncertainties is assumed in the MC ap- 710 The results of a QCD fit depend not only on the input data proach [32]. This comparison is illustrated in Fig. 8. Sim- 711 but also on the input parameters used in the theoretical calilar findings were reported by the MSTW global analy- 712 culations. Nowadays, the PDF groups address the impact of 713 the choices of theoretical parameters by providing alterna-Since the MC method requires large number of repli- 714 tive PDFs with different choices of the mass of the charm cas, the eigenvector representation is often more practi- 715 quarks  $m_c$ , mass of the bottom quarks  $m_b$  and the value of cal to represent PDF uncertainties. As it was illustrated  $\alpha_s(M_Z)$ . Another important issue is the choice of the funcby [93], it is possible to transform MC to eigenvector 717 tional form for the PDFs at the starting scale and the value representation. Tools to perform this transformation are 718 of the starting scale itself. HERAFitter provides possibility provided with HERAFitter and were recently employed 719 of different user choices of various input parameters of the

metric. HERAFitter provides the possibility to use asym- 723 allows to assess the impact of including new data in an exmetric systematic uncertainties. The implementation relies 724 isting fit using the Bayesian Reweighting technique. The method provides a fast estimate of the impact of new data on PDFs. Bayesian Reweighting was first proposed for the PDF sets delivered in form of MC replicas ensembles by [90] and further developed by the NNPDF Collaboration [95, 96]. More recently, a method to preform Bayesian Reweighting studies starting from PDF fits where uncertainties are provided in form of parameter eigenvectors has been also developed [92]. The latter is based on generating replica set by introducing Gaussian fluctuations on the central PDF set with a variance determined by the PDF uncertainty given by the eigenvectors. Both reweighting methods are implemented in HERAFitter.

The Bayesian Reweighting technique relies on the fact that the MC replicas of a PDF sets (i.e. NNPDF) give a representation of the probability distribution in the space of PDFs. In particular, the PDFs are represented as ensembles 749 The QCD calculations based on the DGLAP [6-10] evoof  $N_{\text{rep}}$  equiprobable (i.e. having all weight equal to unity) 750 lution equations are very successful in describing all relereplicas. The central value for a given observable,  $\mathscr{O}(\text{PDF})$ , 751 vant hard scattering data in the perturbative region  $Q^2 \gtrsim$ is computed as the average of the predictions obtained from  $_{752}$  1 GeV<sup>2</sup>. At small-x and small- $Q^2$  the DGLAP dynamics may the ensemble as

$$\langle \mathscr{O}(\text{PDF}) \rangle = \frac{1}{N_{\text{rep}}} \sum_{k=1}^{N_{\text{rep}}} \mathscr{O}(\text{PDF}_k),$$
 (21)

and the uncertainty as the standard deviation of the sample. Upon inclusion of new data the prior probability distribution, given by the prior PDF set, is updated according to Bayes Theorem and the weight of each replica,  $w_k$ , is up-  $_{759}$  6.1 Dipole Models

$$w_k = \frac{(\chi_k^2)^{\frac{1}{2}(N_{\text{data}} - 1)} e^{-\frac{1}{2}\chi_k^2}}{\frac{1}{N_{\text{rep}}} \sum_{k=1}^{N_{\text{rep}}} (\chi_k^2)^{\frac{1}{2}(N_{\text{data}} - 1)} e^{-\frac{1}{2}\chi_k^2}},$$
(22)

specific replica for which the weight is calculated and  $\chi_k^2$  is the chi-square of the new data obtained using the k-th PDF

$$\chi^{2}(m, PDF_{k}) = \sum_{i,i=1}^{N_{\text{data}}} (m_{i} - m_{i}(PDF_{k})) \,\sigma_{ij}^{-1}(m_{j} - m_{j}(PDF_{k})) \,. \tag{23}$$

as the weighted average,

$$\langle \mathcal{O}(\text{PDF}) \rangle = \frac{1}{N_{\text{rep}}} \sum_{k=1}^{N_{\text{rep}}} w_k \mathcal{O}(\text{PDF}_k).$$
 (24)

To simplify the use of reweighted set, an unweighted set (i.e. a set of equiprobable replicas which incorporates the information of the original weights) is generated using the method described in [95].

The number of effective replicas of a reweighted sets, 7777 that is the size of an equiprobable replicas set containing the 778

same amount of information as the reweighted set in question, is measured by the Shannon Entropy

$$N_{\text{eff}} \equiv \exp\left\{\frac{1}{N_{\text{rep}}} \sum_{k=1}^{N} \text{rep} w_k \ln(N_{\text{rep}}/w_k)\right\}. \tag{25}$$

On the one hand there is no reason in generating a final unweighted set that has a number of replicas (significantly) larger than  $N_{\rm eff}$  as no extra information is gained. On the other hand it is advisable to start from a prior PDF set which has as many replicas as possible in order to have a more accurate posterior set at the end of the reweighting procedure.

be modified by non-perturbative QCD effects like saturationbased dipole models and other higher twist effects. Differ-(21) 755 ent approaches that are alternatives to the DGLAP formal-756 ism can be used to analyse DIS data in HERAFitter. These include several different dipole models and the use of transverse momentum dependent, or unintegrated PDFs (uPDFs).

760 The dipole picture provides an alternative approach to the (22) 761 proton-virtual photon scattering at low x providing the de-<sub>762</sub> scription of both inclusive and diffractive processes. In this approach, the virtual photon fluctuates into a  $q\bar{q}$  (or  $q\bar{q}g$ ) where  $N_{\text{data}}$  is the number of new data points, k denotes the 764 dipole which interacts with the proton [97]. The dipoles can 765 be considered as quasi-stable quantum mechanical states, which have very long life time  $\propto 1/m_p x$  and a size which is not changed by scattering. The dynamics of the interaction are embedded in the dipole scattering amplitude.

Several dipole models which assume different behavior of the dipole-proton cross sections are implemented in Given a PDF set and a corresponding set of weights, which TTI HERAFitter: the Golec-Biernat-Wüsthoff (GBW) dipole satdescribes the impact on the same set of the inclusion of new 772 uration model [28], the colour glass condensate approach data, the prediction for a given observable can be computed 773 to the high parton density regime called the Iancu-Itakura-Munier (IIM) dipole model [29] and a modified GBW model which takes into account the effects of DGLAP evolution (24) 776 called the Bartels-Golec-Kowalski (BGK) dipole model [30].

> GBW model: In the GBW model the dipole-proton cross section  $\sigma_{dip}$  is given by

$$\sigma_{\text{dip}}(x, r^2) = \sigma_0 \left( 1 - \exp\left[ -\frac{r^2}{4R_0^2(x)} \right] \right), \tag{26}$$

where r corresponds to the transverse separation between the quark and the antiquark, and  $R_0^2$  is an x-dependent

when the dipole size r is small.

802

sion for the dipole cross section which is based on the Balitsky-Kovchegov equation [98]. The explicit formula for  $\sigma_{dip}$  can be found in [29]. The alternative scale parameter  $\tilde{R}$ ,  $x_0$  and  $\lambda$  are fitted parameters of the model.

**BGK model:** The BGK model is a modification of the GBW model assuming that the spacing  $R_0$  is inverse of the gluon density and taking into account the DGLAP evolution of the latter. The dipole cross section is given

$$\sigma_{\text{dip}}(x, r^2) = \sigma_0 \left( 1 - \exp\left[ -\frac{\pi^2 r^2 \alpha_s(\mu^2) x g(x, \mu^2)}{3\sigma_0} \right] \right).$$
 (27)

The factorisation scale  $\mu^2 = C_{bgk}/r^2 + \mu_0^2$ . The gluon density parametrised at some starting scale  $Q_0^2$  by Eq. 12 is evolved to larger scales using DGLAP evolution. Variables  $\sigma_0$ ,  $\mu_0^2$  and three parameters for the gluon density,  $A_g$ ,  $B_g$ ,  $C_g$ , are fitted parameters of the model, while  $C_{bgk}$ is fixed to 4.0.

# BGK model with valence quarks:

The dipole models are valid in the low-x region only, where the valence quark contribution to the total proton momentum is 5% to 15% for x from 0.0001 to 0.01  $_{842}$ [99]. The new HERA  $F_2$  measurements have a precision which is better than 2%. Therefore, in HERAFitter the contribution of the valence quarks can be taken into account in the original BGK model [100].

# 6.2 Transverse Momentum Dependent PDFs

QCD calculations of multiple-scale processes and complex final-states require in general transverse-momentum dependent (TMD) [101], or unintegrated, parton distribution and 848 parton decay functions [102–110]. The TMD factorisation 849 has been proven recently [101] for inclusive DIS. For particular hadron-hadron scattering processes, like heavy flavor, 851 vector boson and Higgs production, TMD factorisation has 852 also been proven in the high-energy (small-x) limit [111- 853 113]

In the framework of high-energy factorisation [111, 114, 855 115] the DIS cross section can be written as a convolution in 856 both longitudinal and transverse momenta of the TMD parton density function  $\mathcal{A}(x, k_t, \mu)$  with the off-shell partonic matrix elements, as follows

$$\sigma_j(x, Q^2) = \int_x^1 dz \int d^2k_t \ \hat{\sigma}_j(x, Q^2, z, k_t) \ \mathscr{A}(z, k_t, \mu)$$
 (28)

scale parameter which represents the spacing of the glu-  $^{814}$  with the DIS cross sections  $\sigma_j$ , (j=2,L) related to the strucons in the proton.  $R_0^2(x) = (x/x_0)^{\lambda}/1 \text{ GeV}^{-2}$  is called the s15 ture functions  $F_2$  and  $F_L$ . The hard-scattering kernels  $\hat{\sigma}_i$  of saturation radius. The cross-section normalisation  $\sigma_0$ ,  $x_0$ , 816 Eq. 28, are  $k_t$ -dependent and the evolution of the transverseand  $\lambda$  are parameters of the model commonly fitted to 817 momentum dependent gluon density  $\mathscr{A}$  is obtained by comthe DIS data. This model gives exact Bjorken scaling 818 bining the resummation of small-x logarithmic contributions [116– 118] with medium-x and large-x contributions to parton split-IIM model: The IIM model assumes an improved expres- 820 ting [6, 9, 10] according to the CCFM evolution equation [25, 119, 120].

> The factorisation formula (28) allows resummation of logarithmically enhanced small-x contributions to all orders 824 in perturbation theory, both in the hard scattering coefficients and in the parton evolution, fully taking into account the dependence on the factorisation scale  $\mu$  and on the factorisation scheme [121, 122].

> The cross section  $\sigma_i$ , (j = 2, L) is calculated in a FFN scheme, where only the boson-gluon fusion process ( $\gamma^* g^* \rightarrow$  $q\bar{q}$ ) is included. The masses of the quarks are explicitly included as parameters of the model. In addition to  $\gamma^* g^* \to q\bar{q}$ , the contribution from valence quarks is included via  $\gamma^* q \rightarrow q$ by using a CCFM evolution of valence quarks [123, 124].

## **CCFM Grid Techniques:**

844

The CCFM evolution cannot be written easily in an analytic closed form. For this reason a Monte Carlo method is employed, which is however time-consuming, and cannot be used in a straightforward manner in a fit program. Following the convolution method introduced in [124, 125], the kernel  $\tilde{\mathscr{A}}(x'', k_t, p)$  is determined from the Monte Carlo solution of the CCFM evolution equation, and then folded with the non-perturbative starting distribution  $\mathcal{A}_0(x)$ .

$$x\mathscr{A}(x,k_t,p) = x \int dx' \int dx'' \mathscr{A}_0(x') \widetilde{\mathscr{A}}(x'',k_t,p) \,\delta(x'x''-x)$$
$$= \int dx' \mathscr{A}_0(x') \cdot \frac{x}{x'} \,\widetilde{\mathscr{A}}\left(\frac{x}{x'},k_t,p\right), \tag{29}$$

where  $k_t$  denotes the transverse momentum of the propagator gluon and p is the evolution variable.

The kernel  $\tilde{\mathscr{A}}$  incorporates all of the dynamics of the evolution. It is defined on a grid of  $50 \otimes 50 \otimes 50$  bins in  $x, k_t, p$ . The binning in the grid is logarithmic, except for the longitudinal variable x where 40 bins in logarithmic spacing below 0.1, and 10 bins in linear spacing above 0.1 are used.

Calculation of the cross section according to Eq. 28 involves a multidimensional Monte Carlo integration which is time consuming and suffers from numerical fluctuations. This cannot be employed directly in a fit procedure involving the calculation of numerical derivatives in the search for the minimum. Instead the following equation is applied:

$$\sigma(x, Q^2) = \int_x^1 dx_g \mathscr{A}(x_g, k_t, p) \hat{\sigma}(x, x_g, Q^2)$$

$$= \int_x^1 dx' \mathscr{A}_0(x') \cdot \tilde{\sigma}(x/x', Q^2)$$
(30)

859

862

864

866

871

Here, first  $\tilde{\sigma}(x',Q^2)$  is calculated numerically with a Monte were also published by HERA experiments in the inclusive standard fit procedures.

## **Functional Forms for TMD parameterisation:**

the following form is used:

$$x\mathcal{A}_0(x, k_t) = Nx^{-B} \cdot (1 - x)^C \left(1 - Dx + E\sqrt{x}\right) \exp[-k_t^2/\sigma^2]$$
, (31)

Valence quarks are treated using the method of [123] as 913 every scale p.

HERAFitter provided tools or with TMDplotter[35].

## 7 HERAFitter Code Organisation

HERAFitter is an open source code and it can be downloaded from the dedicated webpage [1] together with its sup- 921 9 Summary porting documentation and fast grid theory files (described in section 4) associated with the properly formatted data files 922 The HERAFitter project is a unique platform for QCD analrelevant information to perform QCD fits with HERA DIS 924 fully encapsulates a wide variety of QCD tools to facilitate data as a default set 1. The performance time depends on the 925 analyses of the experimental data and theoretical calculacombination of C++ and Fortran 77 libraries with minimal 929 settings, and a variety of different methodologies in treatdependences are required except QCDNUM evolution program 931 of HERAFitter is driven by the QCD advances in theoreti-[22] and CERN libraries. The ROOT libraries are only re- 932 cal calculations and in precision of experimental data. quired for the drawing tools and when invoking APPLGRID source code.

#### 8 Applications of HERAFitter

The HERAFitter program was used in a number of experimental and theoretical analyses. This list includes several LHC analyses of SM processes, namely inclusive Drell-Yan and Wand Z production [11, 13, 14], inclusive jet production [12]. The results of QCD analyses using HERAFitter

Carlo integration on a grid in x for the values of  $Q^2$  used 902 [15] and the heavy flavour production measurements [16, in the fit. Then the last step in Eq. 30 is performed with 903 126]. Following theory and phenomenology studies were a fast numerical gauss integration, which can be used in 904 performed with HERAFitter: a determination of the trans-905 verse momentum dependent gluon density using precision 906 HERA data [127], an analysis of HERA data within a dipole For the starting distribution  $\mathcal{A}_0$ , at the starting scale  $Q_0$ , 907 model [100], the study of the low-x uncertainties in PDFs determined from the HERA data using different parameter-909 isatons [87] and the impact of QED radiative corrections on  $x\mathscr{A}_0(x,k_t) = Nx^{-B} \cdot (1-x)^C \left(1-Dx+E\sqrt{x}\right) \exp\left[-k_t^2/\sigma^2\right]$ , (31) 910 PDFs [128]. A recent study based on a set of PDFs determined by the set of PD 911 mined with the HERAFitter and addressing the correlated with  $\sigma^2 = Q_0^2/2$  and the free parameters N, B, C, D, E. <sub>912</sub> uncertainties between orders was published in [94].

The HERAFitter framework has been used to produce described in [124] with a starting distribution taken from 914 PDF grids from the QCD analyses performed at HERA [36, any collinear PDF and imposing the flavor sum rule at 915 129] and at the LHC [130], using measurements from AT-916 LAS [11, 12], which can be used to study predictions for The TMD parton densities can be plotted either with 917 SM or beyond SM processes. Moreover, HERAFitter pro-918 vides a possibility to perform impact studies for possible 919 future colliders as demonstrated by the QCD studies at the 920 LHeC [131].

available in HERAFitter. The source code contains all the 923 yses to study the structure of the proton. The project successfitting options and varies from 10 minutes (using 'FAST' 926 tions. HERAFitter is the first open source platform which techniques as described in section 4) to several hours when 927 can be used for benchmarking studies. It allows for direct full uncertainties are estimated. The HERAFitter code is a  $^{928}$  comparisons of various theoretical approaches under the same dependencies, i.e. for the default fitting options no external 930 ing the experimental and model uncertainties.
