Abstract HERAFitter [1] is an open-source package that provides a framework for the determination of the parton distribution functions (PDFs) of the proton and for many different kinds of analyses in Quantum Chromodynamics (QCD). It encodes results from a wide range of experimental (QCD). It encodes results from a wide range of experimental to measurements in lepton-proton deep inelastic scattering and proton-proton (proton-antiproton) collisions at hadron colliders. Those are complemented with a variety of theoretical options for calculating PDF-dependent cross section predictions corresponding to the measurements. The data and the-

$$+ \mathcal{O}\left(\frac{\Lambda_{QCD}^{2}}{Q^{2}}\right)$$
(1)

where the cross section σ is expressed as a convolution of Parton Distribution Functions (PDFs) f_a and f_b with the parton cross section $\hat{\sigma}^{ab}$, involving a momentum transfer qsuch that $Q^2 = |q^2| \gg \Lambda_{QCD}^2$, where Λ_{QCD} is the QCD scale. At Leading-Order (LO) in the perturbative expansion of the strong-coupling constant, the gPDFs represent the probability of finding a specific parton a(b) in the first (second) hadron carrying a fraction x_1 (x_2) of its momentum. The indices a and b in Eq. 1 indicate the various kinds of partons, i.e. gluons, quarks and antiquarks of different flavours that are considered as the constituents of the proton. The PDFs depend on the factorisation scale, μ_F , while the parton cross sections depend on the strong coupling constant, α_s , and the factorisation and renormalisation scales, μ_F and μ_R . The parton cross sections $\hat{\sigma}^{ab}$ are calculable in perturbative QCD (pQCD) whereas PDFs are non-perturbative and are usually constrained by global fits to a variety of experimental data. The assumption that PDFs are universal, within a particular 93 Data: Measurements from various processes are provided factorisation scheme [4-8], is crucial to this procedure. Re- 94 in the HERAFitter package including the information on cent review articles on PDFs can be found in Refs. [9, 10]. 95 their uncorrelated and correlated uncertainties. HERA in-

oretical predictions are brought together through numerous 54 proton-proton (pp) and proton-antiproton $(p\bar{p})$ collisions at at increasingly higher orders, has motivated the development of a tool to combine them together in a fast, efficient, opensource framework.

> This paper describes the open-source QCD fit frame-65 work HERAFitter, which includes a set of tools to facili-72 to test the impact of new experimental data on the PDFs and on the SM parameters.

> This paper is organised as follows: The general structure of HERAFitter is presented in Sec. 2. In Sec. 3 the various processes available in HERAFitter and the corresponding 77 theoretical calculations, performed within the framework of 78 collinear factorisation and the DGLAP [11-15] formalism, are discussed. In Sec. 4 tools for fast calculations of the theoretical predictions are presented. In Sec. 5 the methodology to determine PDFs through fits based on various χ^2 definitions is described. In particular, different treatments of correlated experimental uncertainties are presented. Alternative approaches to the DGLAP formalism are presented 85 in Sec. 6. The organisation of the HERAFitter code is dis-86 cussed in Sec. 7, specific applications of the package are 87 persented in Sec. 8, which is followed by a summary in 88 Sec. 9.

2 The HERAFitter Structure

The diagram in Fig. 1 gives a schematic overview of the $_{\rm 91}$ HERAFitter structure and functionality, which can be di-92 vided into four main blocks:

A precise determination of PDFs as a function of x re- 96 clusive scattering data are sensitive to quark and to gluon kinematic region and that are sensitive to different kinds of $_{98}$ ture function F_L . These data are the basis of any proton PDF partons. Measurements of inclusive Neutral Current (NC) 99 extraction, and are used in all current PDF sets from MSTW and Charge Current (CC) Deep Inelastic Scattering (DIS) 100 [16], CT [17], NNPDF [18], ABM [19], JR [20] and HERAat the lepton-proton (ep) collider HERA provide crucial in- 101 PDF [21] groups. Measurements of charm and beauty quark

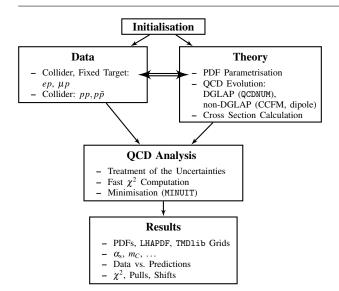

Fig. 1 Schematic overview of the HERAFitter program.

measurements have direct sensitivity to the gluon PDF. However, the kinematic range of HERA data mostly covers low and medium ranges in x. Measurements from the fixed target experiments, the Tevatron and the LHC provide additional constraints on the gluon and quark distributions at high-x, better understanding of heavy quark distributions and decomposition of the light-quark sea. For these purposes, measurements from fixed-target experiments, the Tevatron and 137 to be used by the LHAPDF library [33, 34] or by TMDlib [35]. the LHC can be used.

Fitter framework are listed in Tab. 1.

Theory: The PDFs are parametrised at a starting scale, Q_0^2 , 142 Ref. [21]). Note that following conventions, the PDFs are using a functional form and a set of free parameters **p**. These displayed as parton momentum distributions $xf(x, \mu_F^2)$. PDFs are evolved to the scale of the measurement Q^2 , $Q^2 >$ Q_0^2 . By default, the evolution uses the DGLAP formalism [11-15] as implemented in QCDNUM [22]. Alternatively, the 144 3 Theoretical formalism using DGLAP evolution CCFM evolution [23–26] as implemented in uPDFevolv [27] can be chosen. The prediction of the cross section for a particular process is obtained, assuming factorisation, by the convolution of the evolved PDFs with the corresponding 147 parton scattering cross section. Available theory calculations 148 for each process are listed in Tab. 1. Predictions using dipole models [28–30] can also be obtained.

QCD Analysis: The PDFs are determined in a least squares 152 tions is obtained: fit: a χ^2 function, which compares the input data and theory predictions, is minimised with the MINUIT [31] program. In HERAFitter various choices are available for the treatment of experimental uncertainties in the χ^2 definition. Correlated

As an example, the 140 first set of PDFs extracted using HERAFitter from HERA 141 I data, HERAPDF1.0 [21], is shown in Fig. 2 (taken from

145 In this section the theoretical formalism based on DGLAP [11–15] evolution is described.

A direct consequence of factorisation (Eq. 1) is that the scale dependence or "evolution" of the PDFs can be predicted by the renormalisation group equations. By requiring physical observables to be independent of μ_F , a representation of the parton evolution in terms of the DGLAP equa-

$$\frac{d f_a(x, \mu_F^2)}{d \log \mu_F^2} = \sum_{b=q, \bar{q}, g} \int_x^1 \frac{dz}{z} P_{ab} \left(\frac{x}{z}; \mu_F^2\right) f_b(z, \mu_F^2), \qquad (2)$$

experimental uncertainties can be accounted for using a nui- $_{153}$ where the functions P_{ab} are the evolution kernels or splitsance parameter method or a covariance matrix method as 154 ting functions, which represent the probability of parton a to described in Sec. 5.2. Different statistical assumptions for 155 evolve into parton b. They can be calculated as a perturbathe distributions of the systematic uncertainties, e.g. Gaus- 156 tive expansion in α_s . Once PDFs are determined at the initial sian or LogNormal [32], can also be studied (see Sec. 5.3). scale $\mu_F^2 = Q_0^2$, their evolution to any other scale $Q^2 > Q_0^2$

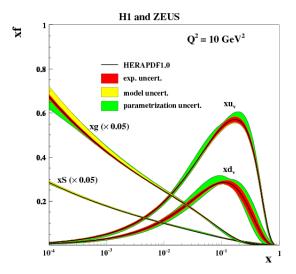

Fig. 2 Distributions of valence (xu_v, xd_v) , sea (xS) and the gluon (g)PDFs in HERAPDF1.0 [21]. The gluon and the sea distributions are scaled down by a factor of 20. The experimental, model and parametrisation uncertainties are shown as coloured bands.

is entirely determined by the DGLAP equations. The PDFs are then used to calculate cross sections for various different processes. Alternative approaches to DGLAP evolution, valid in different kinematic regimes, are also implemented in HERAFitter and will be discussed in Sec. 6.

3.1 Deep Inelastic Scattering and Proton Structure

The formalism that relates the DIS measurements to pQCD and the PDFs has been described in detail in many extensive reviews (see e.g. Ref. [36]) and it is only briefly summarised here. DIS is the process where a lepton scatters off the partons in the proton by a virtual exchanged of a neutral (γ/Z) or charged (W^{\pm}) vector boson and, as a result, a scattered lepton and a multi-hadronic final state are produced. The 212 Zero-Mass Variable Flavour Number (ZM-VFN):

$$\frac{d^2 \sigma_{NC}^{e^{\pm} p}}{dx dQ^2} = \frac{2\pi \alpha^2 Y_+}{x Q^4} \sigma_{r,NC}^{e^{\pm} p},\tag{3}$$

$$\sigma_{r,NC}^{e^{\pm}p} = \tilde{F}_{2}^{\pm} \mp \frac{Y_{-}}{Y_{+}} x \tilde{F}_{3}^{\pm} - \frac{y^{2}}{Y_{+}} \tilde{F}_{L}^{\pm}, \tag{4}$$

pling constant. The generalised structure functions $\tilde{F}_{2,3}$ can 227 batively in the final state. The lowest order process is the

be written as linear combinations of the proton structure functions F_2^{γ} , $F_{2,3}^{\gamma Z}$ and $F_{2,3}^{Z}$, which are associated with pure photon exchange terms, photon-Z interference terms and pure Z exchange terms, respectively. The structure function \tilde{F}_2 is the dominant contribution to the cross section, $x\tilde{F}_3$ becomes important at high Q^2 and \tilde{F}_L is sizable only at high y. In the framework of pQCD, the structure functions are directly related to the PDFs: at LO F_2 is the weighted momentum sum of quark and anti-quark distributions, xF_3 is related to their difference, and F_L vanishes. At higher orders, terms related to the gluon distribution appear, in particular F_L is strongly related to the low-x gluon.

The inclusive CC ep cross section, analogous to the NC ep case, can be expressed in terms of another set of structure 196 functions, \tilde{W} :

$$\frac{d^2 \sigma_{CC}^{e^{\pm} p}}{dx dQ^2} = \frac{1 \pm P}{2} \frac{G_F^2}{2\pi x} \left[\frac{m_W^2}{m_W^2 + Q^2} \right] \sigma_{r,CC}^{e^{\pm} p}$$
 (5)

$$\sigma_{rCC}^{e^{\pm}p} = Y_{+}\tilde{W}_{2}^{\pm} \mp Y_{-}x\tilde{W}_{3}^{\pm} - y^{2}\tilde{W}_{L}^{\pm}, \tag{6}$$

where P represents the lepton beam polarisation. At LO in α_s , the CC e^+p and e^-p cross sections are sensitive to different combinations of the quark flavour densities.

Beyond LO, the QCD predictions for the DIS structure functions are obtained by convoluting the PDFs with appropriate hard-process scattering matrix elements, which are referred to as coefficient functions.

The DIS measurements span a large range of Q^2 from a few GeV² to about 10⁵ GeV², crossing heavy quark mass thresholds, thus the treatment of heavy quark (charm and beauty) production and the chosen values of their masses become important. There are different schemes for the treatment of heavy quark production. Several variants of these $_{ t 210}$ schemes are implemented in HERAFitter and they are briefly 211 discussed below.

common DIS kinematic variables are the scale of the pro- 213 In this scheme [37], the heavy quarks appear as partons in cess Q^2 , which is the absolute squared four-momentum of 214 the proton at Q^2 values above $\sim m_h^2$ (heavy quark mass) and the exchange boson, Bjorken x, which can be related in the 215 they are then treated as massless in both the initial and fiparton model to the momentum fraction that is carried by 216 nal states of the hard scattering process. The lowest order the struck quark, and the inelasticity y. These are related by 217 process is the scattering of the lepton off the heavy quark $y = Q^2/sx$, where s is the squared centre-of-mass (c.o.m.) 218 via electroweak boson exchange. This scheme is expected to be reliable in the region where $Q^2 \gg m_h^2$. In HERAFitter The NC cross section can be expressed in terms of gener- 220 this scheme is available for the DIS structure function cal-221 culation via the interface to the QCDNUM [22] package, thus it benefits from the fast QCDNUM convolution engine.

223 Fixed Flavour Number (FFN):

(4) 224 In this rigorous quantum field theory scheme [38–40], only 225 the gluon and the light quarks are considered as partons where $Y_{\pm}=1\pm(1-y)^2$ and α is the electromagnetic cou- 226 within the proton and massive quarks are produced perturbation. heavy quark-antiquark pair production via boson-gluon fu- 279 sion. In HERAFitter this scheme can be accessed via the 280 QCDNUM implementation or through the interface to the opensource code OPENQCDRAD [41] as implemented by the ABM group. This scheme is reliable for $Q^2 \sim m_h^2$. In QCDNUM, the calculation of the heavy quark contributions to DIS structure functions are available at Next-to-Leading Order (NLO) and only electromagnetic exchange contributions are taken into account. In the OPENQCDRAD implementation the heavy quark contributions to CC structure functions are also available and, for the NC case, the QCD corrections to the coefficient functions in Next-to-Next-to Leading Order (NNLO) are provided in the best currently known approximation [42]. The OPENQCDRAD implementation uses in addition the running heavy quark mass in the \overline{MS} scheme [43].

It is sometimes argued that this scheme reduces the sensitivity of the DIS cross sections to higher order corrections [42]. It is also known to have smaller non-perturbative corrections than the pole mass scheme [44].

General-Mass Variable Flavour Number (GM-VFN):

257

259

271

275

276

277

278

In this scheme [45], heavy quark production is treated for $Q^2 \sim m_h^2$ in the FFN scheme and for $Q^2 \gg m_h^2$ in the massless scheme with a suitable interpolation in between. The details of this interpolation differ between implementations. The groups that use GM-VFN schemes in PDFs are MSTW, CT (CTEQ), NNPDF, and HERAPDF. HERAFitter implements different variants of the GM-VFN scheme.

- GM-VFN Thorne-Roberts scheme: The Thorne-Roberts (TR) scheme [46] was designed to provide a smooth transition from the massive FFN scheme at low scales $Q^2 \gg m_h^2$. Because the original version was technically difficult to implement beyond NLO, it was updated to the TR' scheme [47]. There are two variants of the TR' schemes: TR' standard (as used in MSTW PDF sets [16, 47]) and TR' optimal [48], with a smoother transition across the heavy quark threshold region. Both TR' variants are accessible within the HERAFitter package at LO, NLO and NNLO.
- GM-VFN ACOT scheme: The Aivazis-Collins-Olness- 291 3.3 Diffractive PDFs Tung (ACOT) scheme belongs to the group of VFN fac-

and ACOT-Full schemes is illustrated in Fig. 3 (taken from [21]).

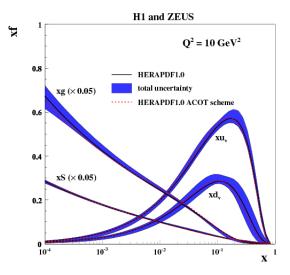

Fig. 3 Distributions of valence (xu_v, xd_v) , sea (xS) and the gluon (g)PDFs in HERAPDF1.0 [21] with their total uncertainties at the scale of $Q^2 = 10 \text{ GeV}^2$ obtained using the TR' scheme and compared to the PDFs obtained with the ACOT-Full scheme using the k-factor technique (red). The gluon and the sea distributions are scaled down by a factor of 20.

281 3.2 Electroweak Corrections to DIS

282 Calculations of higher-order electroweak corrections to DIS 283 at HERA are available in HERAFitter in the on-shell scheme. $Q^2 \sim m_h^2$ to the massless ZM-VFNS scheme at high scales $\frac{200}{284}$ In this scheme, the masses of the gauge bosons m_W and m_Z are treated as basic parameters together with the top, 286 Higgs and fermion masses. These electroweak corrections are based on the EPRC package [53]. The code calculates the running of the electromagnetic coupling α using the most recent parametrisation of the hadronic contribution [54] as well as an older version from Burkhard [55].

torisation schemes that use the renormalisation method 292 About 10% of deep inelastic interactions at HERA are diffracof Collins-Wilczek-Zee (CWZ) [49]. This scheme uni- 293 tive, such that the interacting proton stays intact ($ep \rightarrow eXp$). fies the low scale $Q^2 \sim m_h^2$ and high scale $Q^2 > m_h^2$ re- 294 The proton is well separated from the rest of the hadronic figions in a coherent framework across the full energy 295 nal state by a large rapidity gap. This is interpreted as the range. Within the ACOT package, the following variants $_{296}$ dissociation of the virtual photon into a hadronic system X of the ACOT scheme are available: ACOT-Full [50], S- 297 with a squared invariant mass much smaller than the photon-ACOT- χ [51, 52], ACOT-ZM [50], $\overline{\text{MS}}$ at LO and NLO. 298 proton c.o.m. energy $W^2 = ys - Q^2 + m_p^2(1-y)$, where m_p For the longitudinal structure function higher order cal- 299 is the proton mass. Such a process is often assumed to be culations are also available. A comparison of PDFs ex- 300 mediated by the exchange of a hard Pomeron or a secondary tracted from QCD fits to the HERA data with the TR' 301 Reggeon with vacuum quantum numbers. This factorisable

to diffractive cross sections in a similar way to the determi- 332 parton-parton hard scattering cross section. nation of the standard PDFs [56].

In addition to the usual DIS variables x, Q^2 , extra kine- $_{334}$ The corresponding triple differential CC cross section has matic variables are needed to describe the diffractive pro- 335 the form: cess. These are the squared four-momentum transfer of the exchanged Pomeron or Reggeon, t, and the mass m_X of the diffractively produced final state. In practice, the variable m_X is often replaced by the dimensionless quantity $\beta = \frac{Q^2}{m_X^2 + Q^2 - t}$. In models based on a factorisable Pomeron, β may be viewed at LO as the fraction of the Pomeron longitudinal momen- $_{^{336}}$ where $V_{q_1q_2}$ is the Cabibbo-Kobayashi-Maskawa (CKM) quark tum, x_{IP} , which is carried by the struck parton, $x = \beta x_{IP}$, x_{IP} , mixing matrix and x_{IP} are the W boson mass and dewhere *P* denotes the momentum of the proton.

For the inclusive case, the diffractive cross section reads as:

$$\frac{d^4\sigma}{d\beta \, dQ^2 dx_{IP} \, dt} = \frac{2\pi\alpha^2}{\beta \, Q^4} \, \left(1 + (1-y)^2 \right) \overline{\sigma}^{D(4)}(\beta, Q^2, x_{IP}, t) \qquad (7)^{340}$$

with the "reduced cross section":

$$\overline{\sigma}^{D(4)} = F_2^{D(4)} - \frac{y^2}{1 + (1 - y)^2} F_L^{D(4)}.$$
 (8)

The diffractive structure functions can be expressed as convolutions of calculable coefficient functions with the diffractive quark and gluon distribution functions, which in general depend on x_{IP} , Q^2 , β and t.

The diffractive PDFs [57, 58] in HERAFitter are implemented as a sum of two factorised contributions:

$$\Phi_{IP}(x_{IP},t) f_a^{IP}(\beta,Q^2) + \Phi_{IR}(x_{IP},t) f_a^{IR}(\beta,Q^2),$$
 (9)

where $\Phi(x_{I\!P},t)$ are the Reggeon and Pomeron fluxes. The Reggeon PDFs, f_a^{IR} are fixed as those of the pion, while the Pomeron PDFs, f_a^{IP} , can be obtained from a fit to the data.

3.4 Drell-Yan Processes in pp or $p\bar{p}$ Collisions

The Drell-Yan (DY) process provides valuable information about PDFs. In pp and $p\bar{p}$ scattering, the Z/γ^* and W production probe bi-linear combinations of quarks. Complementary information on the different quark densities can be obtained from the W^{\pm} asymmetry (d, u and their ratio), the ratio of the W and Z cross sections (sensitive to the flavour 360 is sensitive to the high-x gluon PDF (see e.g. Ref. [16]). composition of the quark sea, in particular to the s-quark 361 Therefore this process can be used to improve the determidistribution), and associated W and Z production with heavy ³⁶² nation of the gluon PDF, which is particularly important for quarks (sensitive to c- and b-quark densities). Measurements at large boson transverse momentum $p_T \ge m_{W,Z}$ are potentially sensitive to the gluon distribution [59].

At LO the DY NC cross section triple differential in invariant mass m, boson rapidity y and lepton scattering angle $\cos \theta$ in the parton c.o.m. frame can be written as [60, 61]:

$$\frac{d^3\sigma}{dmdyd\cos\theta} = \frac{\pi\alpha^2}{3ms} \sum_{q} \hat{\sigma}^q(\cos\theta, m)
\times \left[f_q(x_1, m^2) f_{\bar{q}}(x_2, m^2) + (q \leftrightarrow \bar{q}) \right], \quad (10)$$

Pomeron picture has proved remarkably successful in the 329 where s is the squared c.o.m. beam energy, the parton modescription of most of the diffractive data. cay width, respectively.

The simple LO form of these expressions allows for the analytic calculations of integrated cross sections. In both NC and CC expressions the PDFs depend only on the boson rapidity y and invariant mass m, while the integral in $\cos \theta$ can (8) 343 be evaluated analytically even for the case of realistic kinematic cuts.

Beyond LO, the calculations are often time-consuming and Monte Carlo generators are often employed. Currently, the predictions for W and Z/γ^* production are available up to NNLO and the predictions for W, Z in association with 349 heavy flavour quarks is available to NLO.

There are several possibilities to obtain the theoretical (9) 351 predictions for DY production in HERAFitter. The NLO and NNLO calculations are time consuming and k-factor or fast grid techniques must be employed (see Sec. 4 for details), which are interfaced to programs such as MCFM [62– ₃₅₅ 64], available for NLO calculations, or FEWZ [65] and DYNNLO[66] for NLO and NNLO, with electroweak corrections estimated 357 using MCSANC [67, 68].

358 3.5 Jet Production in ep and pp or $p\bar{p}$ Collisions

The cross section for production of high p_T hadronic jets 363 Higgs production and searches for new physics. Jet production cross sections are currently known only to NLO. Calculations for higher-order contributions to jet production in pp collisions are in progress [69–71]. Within HERAFitter, the NLOJet++ program [72, 73] may be used for calculations of jet production. Similarly to the DY case, the calculation is very demanding in terms of computing power. Therefore 370 fast grid techniques are used to facilitate the QCD analyses including jet cross section measurements in ep, pp and $p\bar{p}$ (10) 372 collisions. For details see Sec. 4.

3.6 Top-quark Production in pp or $p\bar{p}$ Collisions

At the LHC, top-quark pairs $(t\bar{t})$ are produced dominantly 422 table of k-factors is computed once for a fixed PDF with the via gg fusion. 4.2 Fast Grid Techniques

465

447 Fast grid techniques exploit the fact that iterative PDF fitting procedures do not impose completely arbitrary changes 449 to the types and shapes of the parameterised functions that 450 represent each PDF. Instead, it can be assumed that a generic Precise measurements require accurate theoretical predic- 451 PDF can be approximated by a set of interpolating functions in order to maximise their impact in PDF fits. Perturba- 452 tions with a sufficient number of judiciously chosen suptive calculations become more complex and time-consuming 453 port points. The accuracy of this approximation is checked at higher orders due to the increasing number of relevant 454 and optimised such that the approximation bias is negligibly Feynman diagrams. The direct inclusion of computationally 455 small compared to the experimental and theoretical accudemanding higher-order calculations into iterative fits is thus 456 racy. This method can be used to perform the time consum-457 ing higher-order calculations (Eq. 1) only once for the set of turbative calculation for small changes in input parameters 458 interpolating functions. Further iterations of the calculation is not necessary at each step of the iteration. Two methods 459 for a particular PDF set are fast, involving only sums over have been developed which take advantage of this to solve 460 the set of interpolators multiplied by factors depending on 461 the PDF. This approach can be used to calculate the cross sections of processes involving one or two hadrons in the initial state and to assess their renormalisation and factorisation scale variation.

This technique was pioneered by the fastNLO project [85] 466 to facilitate the inclusion of time consuming NLO jet cross The k-factors are defined as the ratio of the prediction of a 467 section predictions into PDF fits. boson production. The packages differ in their interpolation 524 and optimisation strategies, but both of them construct ta- 525 bles with grids for each bin of an observable in two steps: 526 in the first step, the accessible phase space in the parton mo- 527 mentum fractions x and the renormalisation and factorisa- 528 tion scales μ_R and μ_F is explored in order to optimise the table size. In the second step the grid is filled for the requested observables. Higher-order cross sections can then be obtained very efficiently from the pre-produced grids while varying externally provided PDF sets, μ_R and μ_F , or the strong coupling $\alpha_s(\mu_R)$. This approach can in principle be extended to arbitrary processes. This requires an interface between the higher-order theory programs and the fast interpolation frameworks. Currently available processes for each package are as follows:

The fastNLO project [85] has been interfaced to the NLOJet++ program [72] for the calculation of jet production in DIS [87] as well as 2- and 3-jet production in hadron-hadron collisions at NLO [73, 88]. Threshold corrections at 2-loop order, which approximate the NNLO for the inclusive jet cross section, have also been included into the framework [89] following Ref. [90]. The latest version of the fastNLO convolution program [91] allows for the creation of tables in which renormalisation and factorisation scales can be varied as a function of two pre-defined observables, e.g. jet transverse momentum p_{\perp} and Q for DIS. Recently, the differential calculation of top-pair production in hadron collisions at approximate NNLO [82] has been interfaced to fastNLO [84]. The fastNLO code is available online [92]. Jet cross section grids computed for the kinematics of various experiments can be downloaded from this site.

5.1 Functional Forms for PDF Parametrisation

The PDFs can be parametrised using several predefined func-584 tional forms and flavour decompositions:

Standard Polynomials: The standard polynomial form is the most commonly used. A polynomial functional form is used to parametrise the x-dependence of the PDFs, where index j denotes each parametrised PDF flavour:

$$xf_i(x) = A_i x^{B_j} (1-x)^{C_j} P_i(x).$$
 (12)

The parametrised PDFs are the valence distributions xu_y and xd_v , the gluon distribution xg, and the u-type and d-type sea, $x\bar{U}$, $x\bar{D}$, where $x\bar{U} = x\bar{u}$, $x\bar{D} = x\bar{d} + x\bar{s}$ at the starting scale, which is chosen below the charm mass threshold. The form of polynomials $P_i(x)$ can be varied. The form $(1 + \varepsilon_i \sqrt{x} +$ $D_i x + E_i x^2$) is used for the HERAPDF [21] with additional constraints relating to the flavour decomposition of the light sea. This parametrisation is termed HERAPDF-style. The polynomial can also be parametrised in the CTEQ-style, where $P_i(x)$ takes the form $e^{a_3x}(1+e^{a_4}x+e^{a_5}x^2)$ and, in contrast to the HERAPDF-style, this is positive by construction. QCD number and momentum sum rules are used to determine the normalisations A for the valence and gluon distributions, and the sum-rule integrals are solved analytically.

Bi-Log-Normal Distributions: This parametrisation is motivated by multi-particle statistics and has the following functional form:

$$xf_j(x) = a_j x^{p_j - b_j \log(x)} (1 - x)^{q_j - d_j \log(1 - x)}.$$
 (13)

dard polynomial form described above, however, numerical 589 cesses available in HERAFitter. This is possible via an inintegration of Eq. 13 is required in order to impose the QCD sum rules. 569

on the Chebyshev polynomials can be employed for the gluon 594 the drawing tools available in HERAFitter. and sea distributions. Polynomials with argument log(x) are considered for better modelling the low-x asymptotic behaviour of those PDFs. The polynomials are multiplied by a factor of (1-x) to ensure that they vanish as $x \to 1$. The resulting parametric form reads

$$xg(x) = A_g (1-x) \sum_{i=0}^{N_g-1} A_{g_i} T_i \left(-\frac{2\log x - \log x_{\min}}{\log x_{\min}} \right),$$
 (14)

$$xS(x) = (1-x) \sum_{i=0}^{N_S-1} A_{S_i} T_i \left(-\frac{2\log x - \log x_{\min}}{\log x_{\min}} \right),$$
 (15)

where T_i are first-type Chebyshev polynomials of order i. 603 The normalisation factor A_g is derived from the momentum 604 sum rule analytically. Values of $N_{g,S}$ to 15 are allowed, however the fit quality is already similar to that of the standardpolynomial parametrisation from $N_{g,S} \ge 5$ and has a similar

number of free parameters. Fig. 5 (taken from [96]) shows ⁵⁸³ a comparison of the gluon distribution obtained with the parametrisation Eqs. 14, 15 to the standard-polynomial one, for $N_{g,S} = 9$.

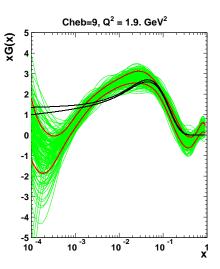

Fig. 5 The gluon density is shown at the starting scale $Q^2 = 1.9 \text{ GeV}^2$. The black lines correspond to the uncertainty band of the gluon distribution using a standard parametrisation and it is compared to the case of the Chebyshev parametrisation [96]. The uncertainty band for the latter case is estimated using the Monte Carlo technique (see Sec. 5.3) with the green lines denoting fits to data replica. Red lines indicate the standard deviation about the mean value of these replicas.

586 External PDFs: HERAFitter also provides the possibility (13) 587 to access external PDF sets, which can be used to compute This function can be regarded as a generalisation of the stan- 588 theoretical predictions for the cross sections for all the proterface to LHAPDF [33, 34] providing access to the global PDF sets. HERAFitter also allows one to evolve PDFs from 592 LHAPDF using QCDNUM. Fig. 6 illustrates a comparison of Chebyshev Polynomials: A flexible parametrisation based 593 various gluon PDFs accessed from LHAPDF as produced with

595 5.2 Representation of χ^2

596 The PDF parameters are determined in HERAFitter by minimisation of a χ^2 function taking into account correlated and uncorrelated measurement uncertainties. There are vari-(14) so our forms of χ^2 , e.g. using a covariance matrix or providing on nuisance parameters to encode the dependence of each cor-(15) 601 related systematic uncertainty for each measured data point. The options available in HERAFitter are the following:

> Covariance Matrix Representation: For a data point μ_i with a corresponding theory prediction m_i , the χ^2 function can be expressed in the following form:

$$\chi^{2}(m) = \sum_{i,k} (m_{i} - \mu_{i}) C_{ik}^{-1}(m_{k} - \mu_{k}), \tag{16}$$

where the experimental uncertainties are given as a covariance matrix C_{ik} for measurements in bins i and k. The covariance matrix C_{ik} is given by a sum of statistical, uncorrelated and correlated systematic contributions:

$$C_{ik} = C_{ik}^{stat} + C_{ik}^{uncor} + C_{ik}^{sys}. (17)$$

Using this representation one cannot distinguish the ef- 651 fect of each source of systematic uncertainty. 652

Nuisance Parameter Representation: In this case, the χ^2 is 653 expressed as

$$\chi^{2}(m,b) = \sum_{i} \frac{\left[\mu_{i} - m_{i}\left(1 - \sum_{j} \gamma_{j}^{i} b_{j}\right)\right]^{2}}{\delta_{i,\text{unc}}^{2} m_{i}^{2} + \delta_{i,\text{stat}}^{2} \mu_{i} m_{i}\left(1 - \sum_{j} \gamma_{j}^{i} b_{j}\right)} + \sum_{j} b_{j}^{2},$$
(18) 659

where, $\delta_{i,\text{stat}}$ and $\delta_{i,\text{unc}}$ are relative statistical and uncorrelated systematic uncertainties of the measurement i. 662 Further, γ^i_j quantifies the sensitivity of the measurement to the correlated systematic source j. The function χ^2 664 depends on the set of systematic nuisance parameters b_j . 665 This definition of the χ^2 function assumes that systematic uncertainties are proportional to the central prediction values (multiplicative uncertainties, $m_i(1-\sum_j \gamma^i_j b_j)$), 669 whereas the statistical uncertainties scale with the square 669 root of the expected number of events. However, additive treatment of uncertainties is also possible in HERA- 671 Fitter.

During the χ^2 minimisation, the nuisance parameters b_j 673 and the PDFs are determined, such that the effect of different sources of systematic uncertainties can be distinguished. 676

Mixed Form Representation: In some cases, the statistical and systematic uncertainties of experimental data are provided in different forms. For example, the correlated experimental systematic uncertainties are available as nuisance parameters, but the bin-to-bin statistical correlations are given in the form of a covariance matrix. HERA-Fitter offers the possibility to include such mixed forms of information.

631

632

634

Any source of measured systematic uncertainty can be treated as additive or multiplicative, as described above. The statistical uncertainties can be included as additive or following the Poisson statistics. Minimisation with respect to nuisance parameters is performed analytically, however, for more detailed studies of correlations individual nuisance parameters can be included into the MINUIT minimisation.

5.3 Treatment of the Experimental Uncertainties

Three distinct methods for propagating experimental uncertainties to PDFs are implemented in HERAFitter and reviewed here: the Hessian, Offset, and Monte Carlo method.

Hessian (Eigenvector) method: The PDF uncertainties reflecting the data experimental uncertainties are estimated by examining the shape of the χ^2 function in the neighbourhood of the minimum [97]. Following the approach of Ref. [97], the Hessian matrix is defined by the second derivatives of χ^2 on the fitted PDF parameters. The matrix is diagonalised and the Hessian eigenvectors are computed. Due to orthogonality these vectors correspond to independent sources of uncertainty in the obtained PDFs.

Offset method: The Offset method [98] uses the χ^2 function for the central fit, but only uncorrelated uncertainties are taken into account. The goodness of the fit can no longer be judged from the χ^2 since correlated uncertainties are ignored. The correlated uncertainties are propagated into the PDF uncertainties by performing variants of the fit with the experimental data varied by $\pm 1\sigma$ from the central value for each systematic source. The resulting deviations of the PDF parameters from the ones obtained in the central fit are statistically independent, and they can be combined in quadrature to derive a total PDF systematic uncertainty.

The uncertainties estimated by the offset method are generally larger than those from the Hessian method.

Monte Carlo method: The Monte Carlo (MC) technique [99, 100] can also be used to determine PDF uncertainties. The uncertainties are estimated using pseudo-data replicas (typically > 100) randomly generated from the

measurement central values and their systematic and statistical uncertainties taking into account all point-to-point correlations. The QCD fit is performed for each replica and the PDF central values and their experimental uncertainties are estimated from the distribution of the PDF parameters obtained in these fits, by taking the mean values and standard deviations over the replicas.

677

678

681

683

686

690

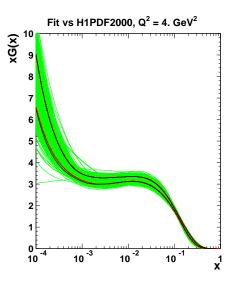

691

693

695

698

The MC method has been checked against the standard error estimation of the PDF uncertainties obtained by the Hessian method. A good agreement was found between the methods provided that Gaussian distributions of statistical and systematic uncertainties are assumed in the MC approach [32]. A comparison is illustrated in Fig. 7. Similar findings were reported by the MSTW global analysis [101].

ployed by the Hessian approach (black lines) and the MC approach 717 PDF sets delivered in the form of MC replicas by [99] and (with more than 100 replicas) assuming Gaussian distribution for uncertainty distributions, shown here for each replica (green lines) together with the evaluated standard deviation (red lines) [32]. The black $\,^{719}$ and red lines in the figure are superimposed because agreement of the 720 studies starting from PDF fits for which uncertainties are methods is so good that it is hard to distinguish them.

Since the MC method requires large number of replicas, the eigenvector representation is a more convenient way to store the PDF uncertainties. It is possible to transform MC to eigenvector representation as shown by [102]. Tools to perform this transformation are provided with HERAFitter and were recently employed for the representation of correlated sets of PDFs at different perturbative orders [103].

The nuisance parameter representation of χ^2 in Eq. 18 is derived assuming symmetric experimental errors, however, the published systematic uncertainties are often asymmetric. HERAFitter provides the possibility to use asymmetric systematic uncertainties. The implementation relies on the

assumption that asymmetric uncertainties can be described by a parabolic function. The nuisance parameter in Eq. 18 is modified as follows

$$\gamma_i^i \to \omega_i^i b_j + \gamma_i^i,$$
 (19)

where the coefficients ω^i_j, γ^i_j are defined from the maximum and minimum shifts of the cross sections due to a variation of the systematic uncertainty j, S_{ij}^{\pm} ,

$$\omega_{j}^{i} = \frac{1}{2} \left(S_{ij}^{+} + S_{ij}^{-} \right), \qquad \gamma_{j}^{j} = \frac{1}{2} \left(S_{ij}^{+} - S_{ij}^{-} \right).$$
 (20)

700 5.4 Treatment of the Theoretical Input Parameters

701 The results of a QCD fit depend not only on the input data but also on the input parameters used in the theoretical calculations. Nowadays, PDF groups address the impact of the choices of theoretical parameters by providing alternative PDFs with different choices of the mass of the charm quarks, m_c , mass of the bottom quarks, m_b , and the value of $\alpha_s(m_Z)$. Other important aspects are the choice of the functional form for the PDFs at the starting scale and the value of the starting scale itself. HERAFitter provides the possibility of different user choices of all these inputs.

5.5 Bayesian Reweighting Techniques

As an alternative to performing a full QCD fit, HERAFitter allows the user to assess the impact of including new data in an existing fit using the Bayesian Reweighting technique. The method provides a fast estimate of the impact of new Fig. 7 Comparison between the standard error calculations as em- 716 data on PDFs. Bayesian Reweighting was first proposed for further developed by the NNPDF Collaboration [104, 105]. More recently, a method to perform Bayesian Reweighting provided in the eigenvector representation has been also developed [101]. The latter is based on generating replica sets by introducing Gaussian fluctuations on the central PDF set with a variance determined by the PDF uncertainty given by the eigenvectors. Both reweighting methods are implemented in HERAFitter.

> The Bayesian Reweighting technique relies on the fact that MC replicas of a PDF set give a representation of the probability distribution in the space of PDFs. In particular, the PDFs are represented as ensembles of N_{rep} equiprobable (i.e. having weights equal to unity) replicas, $\{f\}$. The central value for a given observable, $\mathcal{O}(\{f\})$, is computed as the average of the predictions obtained from the ensemble as

$$\langle \mathcal{O}(\{f\}) \rangle = \frac{1}{N_{\text{rep}}} \sum_{k=1}^{N_{\text{rep}}} \mathcal{O}(f^k),$$
 (21)

and the uncertainty as the standard deviation of the sample. 749 6.1 Dipole Models

Upon inclusion of new data the prior probability distriis updated according to

$$w_k = \frac{(\chi_k^2)^{\frac{1}{2}(N_{\text{data}} - 1)} e^{-\frac{1}{2}\chi_k^2}}{\frac{1}{N_{\text{rep}}} \sum_{k=1}^{N_{\text{rep}}} (\chi_k^2)^{\frac{1}{2}(N_{\text{data}} - 1)} e^{-\frac{1}{2}\chi_k^2}},$$
(22)

where $N_{\rm data}$ is the number of new data points, k denotes the 757 specific replica for which the weight is calculated and χ^2_k is 758 interaction are embedded in a dipole scattering amplitude. the χ^2 of the new data obtained using the k-th PDF replica. 759 Given a PDF set and a corresponding set of weights, which 760 of the dipole-proton cross section, are implemented in HERAdescribes the impact of the inclusion of new data, the pre- 761 Fitter: the Golec-Biernat-Wüsthoff (GBW) dipole saturadiction for a given observable after inclusion of the new data 762 tion model [28], a modified GBW model which takes into can be computed as the weighted average,

$$\langle \mathcal{O}(\{f\}) \rangle = \frac{1}{N_{\text{rep}}} \sum_{k=1}^{N_{\text{rep}}} w_k \mathcal{O}(f^k).$$
 (23)

To simplify the use of a reweighted set, an unweighted set (i.e. a set of equiprobable replicas which incorporates the information contained in the weights) is generated according to the unweighting procedure described in [104]. The number of effective replicas of a reweighted set is measured by its Shannon Entropy [105]

$$N_{\text{eff}} \equiv \exp\left\{\frac{1}{N_{\text{rep}}} \sum_{k=1}^{N_{\text{rep}}} w_k \ln(N_{\text{rep}}/w_k)\right\},\,\,(24)$$

bution, given by theoriginal PDF set, is modified according 750 The dipole picture provides an alternative approach to protonto Bayes Theorem such that the weight of each replica, w_k , 751 virtual photon scattering at low x which can be applied to 752 both inclusive and diffractive processes. In this approach, the virtual photon fluctuates into a $q\bar{q}$ (or $q\bar{q}g$) dipole which interacts with the proton [106, 107]. The dipoles can be con-755 sidered as quasi-stable quantum mechanical states, which have very long life time $\propto 1/m_p x$ and a size which is not changed by scattering with the proton. The dynamics of the

> Several dipole models, which assume different behaviours account the effects of DGLAP evolution, termed the Bartels-764 Golec-Kowalski (BGK) dipole model [30] and the colour ⁷⁶⁵ glass condensate approach to the high parton density regime, named the Iancu-Itakura-Munier (IIM) dipole model [29].

GBW model: In the GBW model the dipole-proton cross section σ_{dip} is given by

$$\sigma_{\text{dip}}(x, r^2) = \sigma_0 \left(1 - \exp\left[-\frac{r^2}{4R_0^2(x)} \right] \right),$$
 (25)

where r corresponds to the transverse separation between the quark and the antiquark, and R_0^2 is an x-dependent scale (24) 769 parameter which represents the spacing of the gluons in the proton. R_0^2 takes the form, $R_0^2(x) = (x/x_0)^{\lambda} 1/\text{GeV}^2$, and is 771 called the saturation radius. The cross-section normalisawhich corresponds to the size of a refitted equiprobable replica, σ_0 , σ_0 , and λ are parameters of the model fitted to the

781 BGK model with valence quarks: The dipole models are valid in the low-x region only, where the valence quark contribution to the total proton momentum is 5% to 15% for x₇₈₄ from 0.0001 to 0.01 [108]. The inclusive HERA measure-QCD calculations based on the DGLAP [11-15] evolution 785 ments have a precision which is better than 2%. Therefore, equations are very successful in describing all relevant hard $_{786}$ HERAFitter provides the option of taking into account the

effects. Different approaches alternative to the DGLAP for- 789 dipole cross section which is based on the Balitsky-Kovchegov malism can be used to analyse DIS data in HERAFitter. 790 equation [109]. The explicit formula for σ_{dip} can be found These include several dipole models and the use of trans- 791 in [29]. The alternative scale parameter \tilde{R} , x_0 and λ are fitted

6.2 Transverse Momentum Dependent PDFs

QCD calculations of multiple-scale processes and complex 835 torisation has also been proven in the high-energy (small-x) are used. limit [119–121] for particular hadron-hadron scattering processes, like heavy flavour, vector boson and Higgs produc- 842 volves a time-consuming multidimensional MC integration, tion.

123] the DIS cross section can be written as a convolution in both longitudinal and transverse momenta of the TMD parton distribution function $\mathcal{A}(x, k_t, \mu_F^2)$ with the off-shell parton scattering matrix elements as follows

$$\sigma_j(x,Q^2) = \int_x^1 dz \int d^2k_t \ \hat{\sigma}_j(x,Q^2,z,k_t) \ \mathscr{A}\left(z,k_t,\mu_F^2\right),$$
 (26)

structure functions F_2 and F_L by $\sigma_i = 4\pi^2 F_i/Q^2$, and the hard-scattering kernels $\hat{\sigma}_i$ of Eq. 26 are k_t -dependent.

The factorisation formula in Eq. 26 allows resummation of logarithmically enhanced small-x contributions to all orders in perturbation theory, both in the hard scattering coefficients and in the parton evolution, fully taking into account the dependence on the factorisation scale μ_F and on the factorisation scheme [124, 125].

811

818

820

Phenomenological applications of this approach require matching of small-x contributions with finite-x contributions. To this end, the evolution of the transverse momentum dependent gluon density A is obtained by combining the resummation of small-x logarithmic corrections [126-128] with⁸⁵⁵ medium-x and large-x contributions to parton splitting [11, 14, 15] according to the CCFM evolution equation [23–26].

The cross section σ_i , (j = 2, L) is calculated in a FFN scheme, using the boson-gluon fusion process ($\gamma^*g^* \to q\bar{q}$). ⁸⁵⁹ The TMD parton densities can be plotted either with HERA-The masses of the quarks are explicitly included as parameters of the model. In addition to $\gamma^* g^* \to q\bar{q}$, the contribution from valence quarks is included via $\gamma^* q \to q$ by using a CCFM evolution of valence quarks [129–131].

CCFM Grid Techniques: The CCFM evolution cannot be written easily in an analytic closed form. For this reason, a MC method is employed, which is, however, time-consuming, and thus cannot be used directly in a fit program.

Following the convolution method introduced in [131, 132], the kernel $\tilde{\mathscr{A}}(x'', k_t, p)$ is determined from the MC solution of the CCFM evolution equation, and then folded with a non-perturbative starting distribution $\mathcal{A}_0(x)$

$$x\mathscr{A}(x,k_t,p) = x\int dx' \int dx'' \mathscr{A}_0(x') \mathscr{\tilde{A}}\left(x'',k_t,p\right) \delta(x'x''-x)$$
 are estimated. The HERAFitter code is a combination of
$$= \int dx' \mathscr{A}_0(x') \frac{x}{x'} \mathscr{\tilde{A}}\left(\frac{x}{x'},k_t,p\right), \tag{27}$$
 HERAPDF1.0 set.

where k_t denotes the transverse momentum of the propagator gluon and p is the evolution variable.

The kernel $\tilde{\mathscr{A}}$ incorporates all of the dynamics of the final-states can necessitate the use of transverse-momentum $_{836}$ evolution. It is defined on a grid of $50 \otimes 50 \otimes 50$ bins in dependent (TMD) [8], or unintegrated parton distribution x, k, p. The binning in the grid is logarithmic, except for and parton decay functions [110–118]. TMD factorisation 838 the longitudinal variable x for which 40 bins in logarithmic has been proven recently [8] for inclusive DIS. TMD fac- 839 spacing below 0.1, and 10 bins in linear spacing above 0.1

Calculation of the cross section according to Eq. 26 inwhich suffers from numerical fluctuations. This cannot be In the framework of high-energy factorisation [119, 122, 844 employed directly in a fit procedure. Instead the following 845 equation is applied:

$$\sigma(x,Q^2) = \int_x^1 dx_g \mathscr{A}(x_g, k_t, p) \hat{\sigma}(x, x_g, Q^2)$$
$$= \int_x^1 dx' \mathscr{A}_0(x') \tilde{\sigma}(x/x', Q^2), \tag{28}$$

where first $\tilde{\sigma}(x',Q^2)$ is calculated numerically with a MC where the DIS cross sections $\sigma_j(j=2,L)$ are related to the strength integration on a grid in x for the values of Q^2 used in the 848 fit. Then the last step in Eq. 28 is performed with a fast numerical Gauss integration, which can be used directly in the

> 851 Functional Forms for TMD parametrisation: For the starting distribution \mathcal{A}_0 , at the starting scale Q_0^2 , the following

$$x\mathscr{A}_0(x,k_t) = Nx^{-B}(1-x)^C \left(1 - Dx + E\sqrt{x}\right)$$
$$\times \exp[-k_t^2/\sigma^2], \tag{29}$$

where $\sigma^2 = Q_0^2/2$ and N, B, C, D, E are free parameters. Valence quarks are treated using the method of Ref. [129] as described in Ref. [131] with a starting distribution taken 857 from any collinear PDF and imposition of the flavour sum 858 rule at every scale p.

Fitter tools or with TMDplotter [35].

861 7 HERAFitter Code Organisation

 $_{\mbox{\scriptsize 862}}$ HERAFitter is an open source code under the GNU gen-863 eral public licence. It can be downloaded from a dedicated webpage [1] together with its supporting documentation and fast grid theory files (described in Sec. 4) associated with 866 data files. The source code contains all the relevant information to perform QCD fits with HERA DIS data as a default set. ¹ The execution time depends on the fitting options and varies from 10 minutes (using "FAST" techniques as described in Sec. 4) to several hours when full uncertainties

¹Default settings in HERAFitter are tuned to reproduce the central

872 C++ and Fortran 77 libraries with minimal dependencies, 907 Fitter and addressing the correlated uncertainties between i.e. for the default fitting options no external dependencies 908 different orders has been published in [103]. An application are required except the QCDNUM evolution program [22]. The 909 of the TMDs obtained with HERAFitter W production at ROOT libraries are only required for the drawing tools and 910 the LHC can be found in [143]. when invoking APPLGRID. The HERAFitter framework has been used to produce

919 9 Summary

920 HERAFitter is the first open-source code designed for stud-921 ies of the structure of the proton. It provides a unique and flexible framework with a wide variety of QCD tools to facilitate analyses of the experimental data and theoretical calculations.

The HERAFitter code, in version 1.1.0, has sufficient 926 options to reproduce the different theoretical choices made 927 in MSTW, CTEQ and ABM fits. This will potentially make it a valuable tool for benchmarking and understanding differences between PDF fits. Such a study would however need to consider a range of further questions, such as the choices of data sets, treatments of uncertainties, input parameter values, χ^2 definitions, etc.

The further progress of HERAFitter is driven by the latest In HERAFitter there are also available cache options for 934 QCD advances in theoretical calculations and in the preci-
