### 1 Introduction

The recent discovery of the Higgs boson [2, 3] and the extensive searches for signals of new physics in LHC proton- 67 of fundamental parameters of QCD such as the heavy quark proton collisions demand high-precision calculations and com<sup>48</sup> masses and the strong coupling constant. It also provides a putations to test the validity of the Standard Model (SM) and 69 common platform for the comparison of different theoretical factorisation in Quantum Chromodynamics (QCD). Using 70 approaches. Furthermore, it can be used to test the impact of collinear factorisation, hadron inclusive cross sections may be written as

$$\sigma(\alpha_{s}(\mu_{R}^{2}), \mu_{R}^{2}, \mu_{F}^{2}) = \sum_{a,b} \int_{0}^{1} dx_{1} dx_{2} f_{a}(x_{1}, \mu_{F}^{2}) f_{b}(x_{2}, \mu_{F}^{2})$$

$$\times \hat{\sigma}^{ab}(x_{1}, x_{2}; \alpha_{s}(\mu_{R}^{2}), \mu_{R}^{2}, \mu_{F}^{2})$$

$$+ \mathcal{O}\left(\frac{\Lambda_{QCD}^{2}}{Q^{2}}\right)$$
(1)

where the cross section  $\sigma$  is expressed as a convolution of Parton Distribution Functions (PDFs)  $f_a$  and  $f_b$  with the parton cross section  $\hat{\sigma}^{ab}$ , involving a momentum transfer q such that  $Q^2 = |q^2| \gg \Lambda_{QCD}^2$ , where  $\Lambda_{QCD}$  is the QCD scale. At Leading-Order (LO), the PDFs represent the probability of finding a specific parton a (b) in the first (second) proton carrying a fraction  $x_1$  ( $x_2$ ) of its momentum. The indices a and b in Eq. 1 indicate the various kinds of partons, i.e. gluons, quarks and antiquarks of different flavours that are considered as the constituents of the proton. The PDFs depend on the factorisation scale,  $\mu_F$ , while the parton cross sections depend on the strong coupling,  $\alpha_s$ , and the factorisation and renormalisation scales,  $\mu_{\rm F}$  and  $\mu_{\rm R}$ . The parton cross sections  $\hat{\sigma}^{ab}$  are calculable in perturbative QCD (pQCD) whereas PDFs are non-perturbative and are usually constrained by global fits to a variety of experimental data. The assumpscheme [4–8], is crucial to this procedure. Recent review ar- 93 in the HERAFitter package including the full information ticles on PDFs can be found in Refs. [9, 10].

quires large amounts of experimental data that cover a wide 96 PDFs through scaling violations and the longitudinal struckinematic region and that are sensitive to different kinds of 97 ture function  $F_L$ . These data are the backbone of any propartons. Measurements of inclusive Neutral Current (NC) 98 ton PDF extraction, and are used by all current PDF groups: and Charge Current (CC) Deep Inelastic Scattering (DIS) 99 MSTW [16], CT [17], NNPDF [18], ABM [19], JR [20], at the lepton-proton (ep) collider HERA provide crucial in- 100 HERAPDF [21]. They can be supplemented by HERA meaformation for determining the PDFs. Different processes in 101 surements sensitive to heavy quarks and by HERA jet mea-

11 oretical predictions are brought together through numerous 54 the LHC and the Tevatron, respectively, provide compleprovides facilities for fits of dipole models and transverse- 58 periments and the corresponding theoretical developments, of a tool to combine them together in a fast, efficient, opensource platform.

> This paper describes the open-source QCD fit platform 64 HERAFitter, which includes a set of tools to facilitate global QCD analyses of pp,  $p\bar{p}$  and ep scattering data. It has been developed for the determination of PDFs and the extraction 71 new experimental data on the PDFs and on the SM parame-72 ters.

This paper is organised as follows: The general structure of HERAFitter is presented in section 2. In section 3 the various processes available in HERAFitter and the corre-<sub>76</sub> sponding theoretical calculations, performed within the framework of collinear factorisation and the DGLAP [11–15] formalism, are discussed. In section 4 tools for fast calculations of the theoretical predictions are presented. In section 5 the methodology to determine PDFs through fits based on various  $\chi^2$  definitions is explained. In particular, different treatments of correlated experimental uncertainties are presented. Alternative approaches to the DGLAP formalism are presented in section 6. The organisation of the HERAFitter 85 code is discussed in section 7, specific applications of the package are persented in section 8, which is followed by a 87 summary in section 9.

### **2 The HERAFitter Structure**

89 The diagram in Fig. 1 gives a schematic overview of the 90 HERAFitter structure and functionality, which can be di-91 vided into four main blocks:

Table 1 The list of experimental data and theory calculations implemented in the HERAFitter package. The references for the individual calculations and schemes are given in the text.

However, the kinematic range of HERA data mostly covers low and medium ranges in x. Improvements in precision of PDFs require additional constraints on the gluon and quark distributions at high-x, better understanding of heavy quark distributions and decomposition of the light- 151 where the functions  $P_{ab}$  are the evolution kernels or splitting Fitter framework are listed in Tab. 1.

112 Theory: The PDFs are parametrised at a starting scale,  $Q_0^2$ , by a chosen functional form with a set of free parameters **p.** These PDFs are evolved to the scale of the measurement  $Q^2$ ,  $Q^2 > Q_0^2$ . By default, the evolution uses the DGLAP 116 formalism [11-15] as implemented in QCDNUM [22]. Alternatively, the CCFM evolution [23-26] as implemented in uPDFevolv [27] can be chosen. The prediction of the cross 119 section for a particular process is obtained, assuming factorisation, by the convolution of the evolved PDFs with the corresponding hard-process parton scattering cross section. Available theory calculations are listed in Tab. 1. Predictions using dipole models [28–30] can also be obtained.

224 QCD Analysis: The PDFs are determined in a least squares fit, minimising a  $\chi^2$  function that is constructed from the input data and theory predictions, with the MINUIT [31] program. In HERAFitter various choices are available for the treatment of experimental uncertainties. Correlated experimental uncertainties can be accounted for using a nuisance parameter method or a covariance matrix method as described in section 5.2. Different statistical assumptions for the distributions of the systematic uncertainties, e.g. Gaussian or LogNormal [32], can also be studied (see section 5.3).

134 Results: The resulting PDFs are provided in a format ready to be used by the LHAPDF library [33, 34] or by TMDlib [35]. HERAFitter drawing tools can be used to display the PDFs with their uncertainties at a chosen scale. As an example, the first set of PDFs extracted using HERAFitter from HERA 139 I data, HERAPDF1.0 [21], is shown in Fig. 2 (taken from 140 Ref. [21]). Note that following conventions, the PDFs are displayed as parton momentum distributions  $xf(x, \mu_F^2)$ .

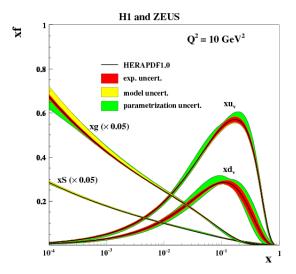

# 142 3 Theoretical formalism using DGLAP evolution

In this section the theoretical formalism based on DGLAP [11–15] evolution is described.

A direct consequence of factorisation (Eq. 1) is that the scale dependence or "evolution" of the PDFs can be predicted by the renormalisation group equations. By requiring physical observables to be independent of  $\mu_{\rm F}$ , a representation of the parton evolution in terms of the DGLAP equa-150 tions is obtained:

$$\frac{d f_a(x, \mu_F^2)}{d \log \mu_F^2} = \sum_{b=q, \bar{q}, g} \int_x^1 \frac{dz}{z} P_{ab} \left(\frac{x}{z}; \mu_F^2\right) f_b(z, \mu_F^2), \qquad (2)$$

quark sea. For these purposes, measurements from fixed- 152 functions, which represent the probability of finding partarget experiments, the Tevatron and the LHC can be used. 153 ton a in parton b. They can be calculated as a perturbative The processes that are currently available within the HERA- 154 expansion in  $\alpha_s$ . Once PDFs are determined at the initial scale  $\mu_F^2 = Q_0^2$ , their evolution to any other scale  $Q^2 > Q_0^2$ 

**Fig. 2** Distributions of valence  $(xu_v, xd_v)$ , sea (xS) and the gluon (g)PDFs in HERAPDF1.0 [21]. The gluon and the sea distributions are scaled down by a factor of 20. The experimental, model and parametrisation uncertainties are shown as coloured bands.

is entirely determined by the DGLAP equations. The PDFs are then used to calculate cross sections for various different processes. Alternative approaches to DGLAP evolution, valid in different kinematic regimes, are also implemented in HERAFitter and will be discussed in section 6.

# 3.1 Deep Inelastic Scattering and Proton Structure

The formalism that relates the DIS measurements to pQCD and the PDFs has been described in detail in many extensive reviews (see e.g. Ref. [36]) and it is only briefly summarised here. DIS is the process where a lepton scatters off the partons in the proton by a virtual exchanged of a neutral  $(\gamma/Z)$ or charged  $(W^{\pm})$  vector boson and, as a result, a scattered lepton and a multi-hadronic final state are produced. The 210 Zero-Mass Variable Flavour Number (ZM-VFN):

$$\frac{d^2 \sigma_{NC}^{e^{\pm} p}}{dx dQ^2} = \frac{2\pi \alpha^2 Y_+}{x Q^4} \sigma_{r,NC}^{e^{\pm} p},\tag{3}$$

$$\sigma_{r,NC}^{e^{\pm}p} = \tilde{F}_2^{\pm} \mp \frac{Y_-}{Y_+} x \tilde{F}_3^{\pm} - \frac{y^2}{Y_+} \tilde{F}_L^{\pm}, \tag{4}$$

pling constant. The generalised structure functions  $\tilde{F}_{2,3}$  can 225 batively in the final state. The lowest order process is the

180 be written as linear combinations of the proton structure functions  $F_2^{\gamma}$ ,  $F_{2,3}^{\gamma Z}$  and  $F_{2,3}^{Z}$ , which are associated with pure photon exchange terms, photon-Z interference terms and pure Z exchange terms, respectively. The structure function  $\tilde{F}_2$ is the dominant contribution to the cross section,  $x\tilde{F}_3$  becomes important at high  $Q^2$  and  $\tilde{F}_L$  is sizable only at high y. In the framework of pQCD the structure functions are directly related to the PDFs, i.e. at leading order (LO)  $F_2$  is the weighted momentum sum of quark and anti-quark distributions,  $xF_3$  is related to their difference, and  $F_L$  vanishes. At higher orders, terms related to the gluon distribution appear, in particular  $F_L$  is strongly related to the low-x gluon. The inclusive CC ep cross section, analogous to the NC ep

case, can be expressed in terms of another set of structure 194 functions,  $\tilde{W}$ :

$$\frac{d^2 \sigma_{CC}^{e^{\pm} p}}{dx dQ^2} = \frac{1 \pm P}{2} \frac{G_F^2}{2\pi x} \left[ \frac{m_W^2}{m_W^2 + Q^2} \right] \sigma_{r,CC}^{e^{\pm} p}$$
 (5)

$$\sigma_{r,CC}^{e^{\pm}p} = Y_{+}\tilde{W}_{2}^{\pm} \mp Y_{-}x\tilde{W}_{3}^{\pm} - y^{2}\tilde{W}_{L}^{\pm},\tag{6}$$

where P represents the lepton beam polarisation. At LO in  $\alpha_s$ , the CC  $e^+p$  and  $e^-p$  cross sections are sensitive to different combinations of the quark flavour densities.

Beyond LO, the QCD predictions for the DIS structure functions are obtained by convoluting the PDFs with appropriate hard-process scattering matrix elements, which are referred to as coefficient functions.

The DIS measurements span a large range of  $Q^2$  from a few GeV<sup>2</sup> to about 10<sup>5</sup> GeV<sup>2</sup>, crossing heavy quark mass thresholds, thus the treatment of heavy quark (charm and beauty) production and the chosen values of their masses become important. There are different schemes for the treatment of heavy quark production. Several variants of these schemes are implemented in HERAFitter and they are briefly 209 discussed below.

common DIS kinematic variables are the scale of the pro- 211 In this scheme [37], the heavy quarks appear as partons in cess  $Q^2$ , which is the absolute squared four-momentum of 212 the proton at  $Q^2$  values above  $\sim m_h^2$  (heavy quark mass) and the exchange boson, Bjorken x, which can be related in the 213 they are then treated as massless in both the initial and fiparton model to the momentum fraction that is carried by 214 nal states of the hard scattering process. The lowest order the struck quark, and the inelasticity y. These are related by 215 process is the scattering of the lepton off the heavy quark  $y = Q^2/sx$ , where s is the squared centre-of-mass (c.o.m.) 216 via electroweak boson exchange. This scheme is expected to be reliable in the region where  $Q^2 \gg m_h^2$ . In HERAFitter The NC cross section can be expressed in terms of gener- 218 this scheme is available for the DIS structure function cal-219 culation via the interface to the QCDNUM [22] package, thus it benefits from the fast QCDNUM convolution engine.

221 Fixed Flavour Number (FFN):

(4) 222 In this rigorous quantum field theory scheme [38–40], only 223 the gluon and the light quarks are considered as partons where  $Y_{\pm}=1\pm(1-y)^2$  and  $\alpha$  is the electromagnetic cou-  $^{224}$  within the proton and massive quarks are produced perturbation. heavy quark-antiquark pair production via boson-gluon fu- 277 sion. In HERAFitter this scheme can be accessed via the 278 QCDNUM implementation or through the interface to the opensource code OPENQCDRAD [41] as implemented by the ABM group. This scheme is reliable for  $Q^2 \sim m_h^2$ . In QCDNUM, the calculation of the heavy quark contributions to DIS structure functions are available at Next-to-Leading Order (NLO) and only electromagnetic exchange contributions are taken into account. In the OPENQCDRAD implementation the heavy quark contributions to CC structure functions are also available and, for the NC case, the QCD corrections to the coefficient functions in Next-to-Next-to Leading Order (NNLO) are provided in the best currently known approximation [42]. The OPENQCDRAD implementation uses in addition the running heavy quark mass in the  $\overline{MS}$  scheme [43].

It is sometimes argued that this scheme reduces the sensitivity of the DIS cross sections to higher order corrections [42]. It is also known to have smaller non-perturbative corrections than the pole mass scheme [44].

General-Mass Variable Flavour Number (GM-VFN):

In this scheme [45], heavy quark production is treated for  $Q^2 \sim m_h^2$  in the FFN scheme and for  $Q^2 \gg m_h^2$  in the massless scheme with a suitable interpolation in between. The details of this interpolation differ between implementations. The PDF groups that use GM-VFN schemes are MSTW, CT (CTEQ), NNPDF, and HERAPDF. HERAFitter implements different variants of the GM-VFN scheme.

GM-VFN Thorne-Roberts scheme: The Thorne-Roberts (TR) scheme [46] was designed to provide a smooth transition from the massive FFN scheme at low scales  $Q^2 \gg m_h^2$ . Because the original version was technically difficult to implement beyond NLO, it was updated to the TR' scheme [47]. There are two variants of the TR' schemes: TR' standard (as used in MSTW PDF sets [16, 47]) and TR' optimal [48], with a smoother transition across the heavy quark threshold region. Both TR' variants are accessible within the HERAFitter package at LO, NLO and NNLO.

GM-VFN ACOT scheme: The Aivazis-Collins-Olness- 289 3.3 Diffractive PDFs Tung (ACOT) scheme belongs to the group of VFN fac-

and ACOT-Full schemes is illustrated in Fig. 3 (taken from [21]).

**Fig. 3** Distributions of valence  $(xu_v, xd_v)$ , sea (xS) and the gluon (g)PDFs in HERAPDF1.0 [21] with their total uncertainties at the scale of  $Q^2 = 10 \text{ GeV}^2$  obtained using the TR' scheme and compared to the PDFs obtained with the ACOT-Full scheme using the k-factor technique (red). The gluon and the sea distributions are scaled down by a factor of 20.

# 279 3.2 Electroweak Corrections to DIS

280 Calculations of higher-order electroweak corrections to DIS 281 at HERA are available in HERAFitter in the on-shell scheme.  $Q^2 \sim m_h^2$  to the massless ZM-VFNS scheme at high scales  $\frac{201}{282}$  In this scheme, the masses of the gauge bosons  $m_W$  and  $m_Z$  are treated as basic parameters together with the top, <sup>284</sup> Higgs and fermion masses. These electroweak corrections are based on the EPRC package [53]. The code calculates the running of the electromagnetic coupling  $\alpha$  using the most recent parametrisation of the hadronic contribution [54] as well as an older version from Burkhard [55].

torisation schemes that use the renormalisation method 290 About 10% of deep inelastic interactions at HERA are diffracof Collins-Wilczek-Zee (CWZ) [49]. This scheme uni- 291 tive, such that the interacting proton stays intact ( $ep \rightarrow eXp$ ). fies the low scale  $Q^2 \sim m_h^2$  and high scale  $Q^2 > m_h^2$  re- 292 The proton is well separated from the rest of the hadronic figions in a coherent framework across the full energy 293 nal state by a large rapidity gap. This is interpreted as the range. Within the ACOT package, the following variants  $_{294}$  dissociation of the virtual photon into a hadronic system X of the ACOT scheme are available: ACOT-Full [50], S- 295 with a squared invariant mass much smaller than the photon-ACOT- $\chi$  [51, 52], ACOT-ZM [50],  $\overline{\text{MS}}$  at LO and NLO. 296 proton c.o.m. energy  $W^2 = ys - Q^2 + m_p^2(1-y)$ , where  $m_p$ For the longitudinal structure function higher order cal- 297 is the proton mass. Such a process is often assumed to be culations are also available. A comparison of PDFs ex- 298 mediated by the exchange of a hard Pomeron or a secondary tracted from QCD fits to the HERA data with the TR' 299 Reggeon with vacuum quantum numbers. This factorisable

Pomeron picture has proved remarkably successful in the  $326 \cos \theta$  in the parton c.o.m. frame can be written as [60, 61]: description of most of the diffractive data. Diffractive parton distributions (DPDFs) can be determined from QCD fits to diffractive cross sections in a similar way to the determination of the standard PDFs [56].

In addition to the usual DIS variables x,  $Q^2$ , extra kinematic variables are needed to describe the diffractive process. These are the squared four-momentum transfer of the exchanged Pomeron or Reggeon, t, and the mass  $m_X$  of the diffractively produced final state. In practice, the variable  $m_X$  is often replaced by the dimensionless quantity  $\beta = \frac{Q^2}{m_X^2 + Q^2 \sin^2}$ . The corresponding triple differential CC cross section has In models based on a factorisable Pomeron,  $\beta$  may be viewed 333 the form: at LO as the fraction of the Pomeron longitudinal momentum,  $x_{IP}$ , which is carried by the struck parton,  $x = \beta x_{IP}$ , where *P* denotes the momentum of the proton.

For the inclusive case, the diffractive cross-section reads as:

$$\frac{d^4\sigma}{d\beta\,dQ^2dx_{IP}dt} = \frac{2\pi\alpha^2}{\beta\,Q^4}\,\left(1 + (1-y)^2\right)\overline{\sigma}^{D(4)}(\beta,Q^2,x_{IP},t) \tag{7}$$

with the "reduced cross-section":

$$\overline{\sigma}^{D(4)} = F_2^{D(4)} - \frac{y^2}{1 + (1 - y)^2} F_L^{D(4)}.$$
 (8)

convolutions of calculable coefficient functions with the diffraçe matic cuts. tive quark and gluon distribution functions, which in general 343 depend on  $x_{IP}$ ,  $Q^2$ ,  $\beta$  and t.

The diffractive PDFs [57, 58] in HERAFitter are implemented as a sum of two factorised contributions:

$$\Phi_{IP}(x_{IP},t) f_a^{IP}(\beta,Q^2) + \Phi_{IR}(x_{IP},t) f_a^{IR}(\beta,Q^2),$$
 (9)

where  $\Phi(x_{IP},t)$  are the Reggeon and Pomeron fluxes. The Reggeon PDFs,  $f_a^{IR}$  are fixed as those of the pion, while the Pomeron PDFs,  $f_a^{IP}$ , can be obtained from a fit to the data.

### 3.4 Drell-Yan Processes in pp or $p\bar{p}$ Collisions

The Drell-Yan (DY) process provides valuable information about PDFs. In pp and  $p\bar{p}$  scattering, the  $Z/\gamma^*$  and W pro-  $_{356}$  3.5 Jet Production in ep and pp or  $p\bar{p}$  Collisions duction probe bi-linear combinations of quarks. Completially sensitive to the gluon distribution [59].

variant mass m, boson rapidity y and lepton scattering angle 366 of jet production. Similarly to the DY case, the calculation

$$\frac{d^3\sigma}{dmdyd\cos\theta} = \frac{\pi\alpha^2}{3ms} \sum_{q} \hat{\sigma}^q(\cos\theta, m) 
\times \left[ f_q(x_1, m^2) f_{\bar{q}}(x_2, m^2) + (q \leftrightarrow \bar{q}) \right], \quad (10)$$

where s is the squared c.o.m. beam energy, the parton momentum fractions are given by  $x_{1,2} = \frac{m}{\sqrt{s}} \exp(\pm y), f_q(x_1, m^2)$ are the PDFs at the scale of the invariant mass, and  $\hat{\sigma}^q$  is the parton-parton hard scattering cross section.

$$\frac{d^3\sigma}{dmdyd\cos\theta} = \frac{\pi\alpha^2}{48s\sin^4\theta_W} \frac{m^3(1-\cos\theta)^2}{(m^2-m_W^2) + \Gamma_W^2 m_W^2} \times \sum_{q_1,q_2} V_{q_1q_2}^2 f_{q_1}(x_1,m^2) f_{q_2}(x_2,m^2), \tag{11}$$

 $_{\mbox{\scriptsize 334}}$  where  $V_{q_1q_2}$  is the Cabibbo-Kobayashi-Maskawa (CKM) quark (7)  $_{335}$  mixing matrix and  $m_W$  and  $\Gamma_W$  are the W boson mass and de-336 cay width, respectively.

The simple LO form of these expressions allows for the analytic calculations of integrated cross sections. In both NC and CC expressions the PDFs depend only on the boson rapidity y and invariant mass m, while the integral in  $\cos \theta$  can The diffractive structure functions can be expressed as 341 be evaluated analytically even for the case of realistic kine-

> Beyond LO, the calculations are often time-consuming and Monte Carlo generators are often employed. Currently, the predictions for W and  $Z/\gamma^*$  production are available up 346 to NNLO and the predictions for W, Z in association with 347 heavy flavour quarks is available to NLO.

There are several possibilities to obtain the theoretical predictions for DY production in HERAFitter. The NLO and NNLO calculations are time consuming and k-factor or fast grid techniques must be employed (see section 4 for details), which are interfaced to programs such as MCFM [62-<sub>353</sub> 64], available for NLO calculations, or FEWZ [65] and DYNNLO[66] 354 for NLO and NNLO, with electroweak corrections estimated 355 using MCSANC [67, 68].

mentary information on the different quark densities can be  $_{357}$  The cross section for production of high  $p_T$  hadronic jets obtained from the  $W^{\pm}$  asymmetry (d, u and their ratio), the 358 is sensitive to the high-x gluon PDF (see e.g. Ref. [16]). ratio of the W and Z cross sections (sensitive to the flavour 359 Therefore this process can be used to improve the determicomposition of the quark sea, in particular to the s-quark 360 nation of the gluon PDF, which is particularly important for distribution), and associated W and Z production with heavy 361 Higgs production and searches for new physics. 367 is very demanding in terms of computing power. Therefore 413 4.1 k-factor Technique fast grid techniques are used to facilitate the QCD analyses including jet cross section measurements in ep, pp and  $p\bar{p}$ collisions. For details see section 4.

### 3.6 Top-quark Production in pp or $p\bar{p}$ Collisions

At the LHC, top-quark pairs  $(t\bar{t})$  are produced dominantly via gg fusion. Thus, LHC measurements of the  $t\bar{t}$  cross section provide additional constraints on the gluon distribution at medium to high values of x, on  $\alpha_s$  and on the top-quark mass,  $m_t$  [74]. Precise predictions for the total inclusive  $t\bar{t}$ cross section are available up to NNLO [75, 76]. Currently, they can be computed within HERAFitter via an interface to the program HATHOR [77].

section at NLO can be obtained by using the program MCFM [64,00 culation at each step, but still requires typically a few re-78-81] interfaced to HERAFitter with *fast grid* techniques. <sub>431</sub> evaluations.

Single top quarks are produced by exchanging electroweak tion can be used, for example, to probe the ratio of the u and u and u for heavy quarks in DIS. "FAST" heavy-flavour schemes are d distributions in the proton as well as the b-quark PDF. nique. Both are available in HERAFitter.

The k-factors are defined as the ratio of the prediction of a higher-order (slow) pQCD calculation to a lower-order (fast) calculation using the same PDF. Because the k-factors depend on the phase space probed by the measurement, they have to be stored including their dependence on the relevant kinematic variables. Before the start of a fitting procedure, a table of k-factors is computed once for a fixed PDF with the time consuming higher-order code. In subsequent iteration 422 steps the theory prediction is derived from the fast lowerorder calculation by multiplying the pre-tabulated k-factors.

This procedure, however, neglects the fact that the kfactors are PDF dependent, and as a consequence, they have 426 to be re-evaluated for the newly determined PDF at the end of the fit for a consistency check. The fit must be repeated 428 until input and output k-factors have converged. In sum-Fixed-order QCD predictions for the differential  $t\bar{t}$  cross mary, this technique avoids iteration of the higher-order cal-

In HERAFitter, the *k*-factor technique is also used for bosons and the measurement of their production cross sec- 433 the fast computation of the time-consuming GM-VFN schemes less quarks, e.g. NLO (massive)/NLO (massless). However, for the ACOT scheme, due to exceptionthreshold resummation beyond the leading logarithmic ap- 442 ally long computation times, the k-factors are used in the

## 4.4 4.2 Fast Grid Techniques

445 Fast grid techniques exploit the fact that iterative PDF fit-446 ting procedures do not impose completely arbitrary changes 447 to the types and shapes of the parameterised functions that represent each PDF. Instead, it can be assumed that a generic 449 PDF can be approximated by a set of interpolating func-450 tions with a sufficient number of judiciously chosen sup-Precise measurements require accurate theoretical predic- 451 port points. The accuracy of this approximation is checked tions in order to maximise their impact in PDF fits. Perturba- 452 and optimised such that the approximation bias is negligibly tive calculations become more complex and time-consuming 453 small compared to the experimental and theoretical accuat higher orders due to the increasing number of relevant 454 racy. This method can be used to perform the time consum-Feynman diagrams. The direct inclusion of computationally 455 ing higher-order calculations (Eq. 1) only once for the set of demanding higher-order calculations into iterative fits is thus 456 interpolating functions. Further iterations of the calculation not possible currently. However, a full repetition of the per- 457 for a particular PDF set are fast, involving only sums over turbative calculation for small changes in input parameters 458 the set of interpolators multiplied by factors depending on is not necessary at each step of the iteration. Two methods 459 the PDF. This approach can be used to calculate the cross have been developed which take advantage of this to solve 460 sections of processes involving one or two hadrons in the the problem: the k-factor technique and the fast grid tech- 461 initial state and to assess their renormalisation and factori-462 sation scale variation.

This technique was pioneered by the fastNLO project [85]16 to facilitate the inclusion of time consuming NLO jet cross 517 section predictions into PDF fits. The APPLGRID [86] project 518 developed an alternative method and, in addition to jets, ex- 519 tended its applicability to other scattering processes, such 520 as DY and heavy quark pair production in association with 521 boson production. The packages differ in their interpolation 522 and optimisation strategies, but both of them construct ta- 523 bles with grids for each bin of an observable in two steps: 524 in the first step, the accessible phase space in the parton mo- 525 mentum fractions x and the renormalisation and factorisa- 526 tion scales  $\mu_R$  and  $\mu_F$  is explored in order to optimise the table size. In the second step the grid is filled for the requested observables. Higher-order cross sections can then be obtained very efficiently from the pre-produced grids while varying externally provided PDF sets,  $\mu_R$  and  $\mu_F$ , or the strong coupling  $\alpha_s(\mu_R)$ . This approach can in principle be extended to arbitrary processes. This requires an interface between the higher-order theory programs and the fast interpolation frameworks. Currently available processes for each package are as follows:

The fastNLO project [85] has been interfaced to the NLOJet++ program [72] for the calculation of jet production in DIS [87] as well as 2- and 3-jet production in hadron-hadron collisions at NLO [73, 88]. Threshold corrections at 2-loop order, which approximate the NNLO for the inclusive jet cross section, have also been included into the framework [89] following Ref. [90]. The latest version of the fastNLO convolution program [91] allows for the creation of tables in which renormalisation and factorisation scales can be varied as a function of two pre-defined observables, e.g. jet transverse momentum  $p_{\perp}$  and Q for DIS. Recently, the differential calculation of top-pair production in hadron collisions at approximate NNLO [82] has been interfaced to fastNLO [84]. The fastNLO code is available online [92]. Jet cross-section grids computed for the kinematics of various experiments can be downloaded from this 527 5 Fit Methodology

GRID tables, and independent variation of  $\alpha_S$  is also allowed. For higher-order predictions, the k-factors technique can also be applied within the APPLGRID framework.

As an example, the HERAFitter interface to APPLGRID was used by the ATLAS [94] and CMS [95] collaborations to extract the strange quark distribution of the proton. The ATLAS strange PDF extracted employing these techniques is displayed in Fig. 4 together with a comparison to the global PDF sets CT10 [17] and NNPDF2.1 [18] (taken from [94]).

### 5.1 Functional Forms for PDF Parametrisation

The PDFs can be parametrised using several predefined func- for  $N_{g,S} = 9$ . tional forms and flavour decompositions:

Standard Polynomials: The standard polynomial form is the most commonly used. A polynomial functional form is used to parametrise the x-dependence of the PDFs, where index j denotes each parametrised PDF flavour:

$$xf_{i}(x) = A_{i}x^{B_{j}}(1-x)^{C_{j}}P_{i}(x).$$
(12)

The parametrised PDFs are the valence distributions  $xu_y$  and  $xd_v$ , the gluon distribution xg, and the u-type and d-type sea,  $x\bar{U}$ ,  $x\bar{D}$ , where  $x\bar{U} = x\bar{u}$ ,  $x\bar{D} = x\bar{d} + x\bar{s}$  at the starting scale, which is chosen below the charm mass threshold. The form of polynomials  $P_i(x)$  can be varied. The form  $(1 + \varepsilon_i \sqrt{x} +$  $D_i x + E_i x^2$ ) is used for the HERAPDF [21] with additional constraints relating to the flavour decomposition of the light sea. This parametrisation is termed HERAPDF-style. The polynomial can also be parametrised in the CTEQ-style, where  $P_i(x)$  takes the form  $e^{a_3x}(1+e^{a_4}x+e^{a_5}x^2)$  and, in contrast to the HERAPDF-style, this is positive by construction. QCD number and momentum sum rules are used to determine the normalisations A for the valence and gluon distributions, and the sum-rule integrals are solved analytically.

Bi-Log-Normal Distributions: This parametrisation is motivated by multi-particle statistics and has the following functional form:

$$xf_j(x) = a_j x^{p_j - b_j \log(x)} (1 - x)^{q_j - d_j \log(1 - x)}.$$
 (13)

dard polynomial form described above, however, numerical integration of Eq. 13 is required in order to impose the QCD sum rules.

Chebyshev Polynomials: A flexible parametrisation based on the Chebyshev polynomials can be employed for the gluon the drawing tools available in HERAFitter. and sea distributions. Polynomials with argument log(x) are considered for better modelling the low-x asymptotic behaviour of those PDFs. The polynomials are multiplied by a factor of (1-x) to ensure that they vanish as  $x \to 1$ . The PDF parameters are determined in HERAFitter by minresulting parametric form reads

$$xg(x) = A_g (1-x) \sum_{i=0}^{N_g-1} A_{g_i} T_i \left( -\frac{2\log x - \log x_{\min}}{\log x_{\min}} \right), \quad (14)$$

$$xS(x) = (1-x)\sum_{i=0}^{N_S-1} A_{S_i} T_i \left( -\frac{2\log x - \log x_{\min}}{\log x_{\min}} \right),$$
 (15)

In this section we describe the available options for the  $_{575}$  where  $T_i$  are first-type Chebyshev polynomials of order i. polynomial parametrisation from  $N_{g,S} \ge 5$  and has a similar number of free parameters. Fig. 5 (taken from [96]) shows a comparison of the gluon distribution obtained with the parametrisation Eqs. 14, 15 to the standard-polynomial one,

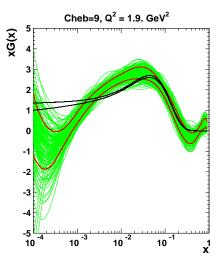

Fig. 5 The gluon density is shown at the starting scale  $Q^2 = 1.9 \text{ GeV}^2$ . The black lines correspond to the uncertainty band of the gluon distribution using a standard parametrisation and it is compared to the case of the Chebyshev parametrisation [96]. The uncertainty band for the latter case is estimated using the Monte Carlo technique (see section 5.3) with the green lines denoting fits to data replica. Red lines indicate the standard deviation about the mean value of these replicas.

584 External PDFs: HERAFitter also provides the possibility (13) 585 to access external PDF sets, which can be used to compute theoretical predictions for the cross sections for all the pro-This function can be regarded as a generalisation of the stan-  $_{587}$  cesses available in HERAFitter. This is possible via an in-588 terface to LHAPDF [33, 34] providing access to the global PDF sets. HERAFitter also allows one to evolve PDFs from 590 LHAPDF using QCDNUM. Fig. 6 illustrates a comparison of various gluon PDFs accessed from LHAPDF as produced with

Covariance Matrix Representation: For a data point  $\mu_i$  with 640 can be included into the MINUIT minimisation. a corresponding theory prediction  $m_i$ , the  $\chi^2$  function can be expressed in the following form:

$$\chi^{2}(m) = \sum_{i,k} (m_{i} - \mu_{i}) C_{ik}^{-1}(m_{k} - \mu_{k}), \tag{16}$$

variance matrix  $C_{ik}$  for measurements in bins i and k. The viewed here: the Hessian, Offset, and Monte Carlo method. covariance matrix  $C_{ik}$  is given by a sum of statistical, uncorrelated and correlated systematic contributions:

$$C_{ik} = C_{ik}^{stat} + C_{ik}^{uncor} + C_{ik}^{sys}. (17)$$

Using this representation one cannot distinguish the ef- 648 fect of each source of systematic uncertainty.

*Nuisance Parameter Representation:* In this case, the  $\chi^2$  is expressed as

$$\chi^{2}(m,b) = \sum_{i} \frac{\left[\mu_{i} - m_{i}\left(1 - \sum_{j} \gamma_{j}^{i} b_{j}\right)\right]^{2}}{\delta_{i,\text{unc}}^{2} m_{i}^{2} + \delta_{i,\text{stat}}^{2} \mu_{i} m_{i}\left(1 - \sum_{j} \gamma_{j}^{i} b_{j}\right)} + \sum_{j} b_{j}^{2},$$
(18)

where,  $\delta_{i, \text{stat}}$  and  $\delta_{i, \text{unc}}$  are relative statistical and uncorrelated systematic uncertainties of the measurement i. 660 Further,  $\gamma_i^i$  quantifies the sensitivity of the measurement 661 to the correlated systematic source j. The function  $\chi^2$  662 depends on the set of systematic nuisance parameters  $b_i$ . 663 This definition of the  $\chi^2$  function assumes that systematic uncertainties are proportional to the central predic- 665 tion values (multiplicative uncertainties,  $m_i(1-\sum_j \gamma_i^j b_j)$ ), 666 whereas the statistical uncertainties scale with the square 667

root of the expected number of events. However, additive treatment of uncertainties is also possible in HERA-Fitter.

During the  $\chi^2$  minimisation, the nuisance parameters  $b_j$ and the PDFs are determined, such that the effect of different sources of systematic uncertainties can be distin-

Mixed Form Representation: In some cases, the statistical and systematic uncertainties of experimental data are provided in different forms. For example, the correlated experimental systematic uncertainties are available as nuisance parameters, but the bin-to-bin statistical correlations are given in the form of a covariance matrix. HERA-Fitter offers the possibility to include such mixed forms of information.

Any source of measured systematic uncertainty can be treated as additive or multiplicative, as described above. The statistical uncertainties can be included as additive or following the Poisson statistics. Minimisation with respect to nuisance parameters is performed analytically, however, for more detailed studies of correlations individual nuisance parameters

# $(16)^{-641}$ 5.3 Treatment of the Experimental Uncertainties

Three distinct methods for propagating experimental uncerwhere the experimental uncertainties are given as a co-  $_{643}$  tainties to PDFs are implemented in HERAFitter and re-

> Hessian (Eigenvector) method: The PDF uncertainties reflecting the data experimental uncertainties are estimated by examining the shape of the  $\chi^2$  function in the neighbourhood of the minimum [97]. Following the approach of Ref. [97], the Hessian matrix is defined by the second derivatives of  $\chi^2$  on the fitted PDF parameters. The matrix is diagonalised and the Hessian eigenvectors are computed. Due to orthogonality these vectors correspond to independent sources of uncertainty in the obtained PDFs.

> Offset method: The Offset method [98] uses the  $\chi^2$  function for the central fit, but only uncorrelated uncertainties are taken into account. The goodness of the fit can no longer be judged from the  $\chi^2$  since correlated uncertainties are ignored. The correlated uncertainties are propagated into the PDF uncertainties by performing variants of the fit with the experimental data varied by  $\pm 1\sigma$  from the central value for each systematic source. The resulting deviations of the PDF parameters from the ones obtained in the central fit are statistically independent, and they can be combined in quadrature to derive a total PDF systematic uncertainty.

The uncertainties estimated by the offset method are generally larger than those from the Hessian method.

693

694

695

Monte Carlo method: The Monte Carlo (MC) technique [99, 100] can also be used to determine PDF uncertainties. The uncertainties are estimated using pseudo-data replicas (typically > 100) randomly generated from the measurement central values and their systematic and statistical uncertainties taking into account all point-to-point correlations. The QCD fit is performed for each replica and the PDF central values and their experimental uncertainties are estimated from the distribution of the PDF parameters obtained in these fits, by taking the mean values and standard deviations over the replicas.

The MC method has been checked against the standard error estimation of the PDF uncertainties obtained by the Hessian method. A good agreement was found between the methods provided that Gaussian distributions of statistical and systematic uncertainties are assumed in the MC approach [32]. A comparison is illustrated in Fig. 7. Similar findings were reported by the MSTW 698 5.4 Treatment of the Theoretical Input Parameters global analysis [101].

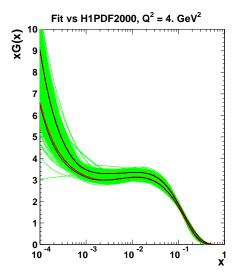

Fig. 7 Comparison between the standard error calculations as employed by the Hessian approach (black lines) and the MC approach  $^{715}\,$ (with more than 100 replicas) assuming Gaussian distribution for un- 716 further developed by the NNPDF Collaboration [104, 105]. certainty distributions, shown here for each replica (green lines) together with the evaluated standard deviation (red lines) [32]. The black and red lines in the figure are superimposed because agreement of the methods is so good that it is hard to distinguish them.

to store the PDF uncertainties. It is possible to transform 724 mented in HERAFitter. MC to eigenvector representation as shown by [102]. Tools to perform this transformation are provided with HERAFitter and were recently employed for the repre-

sentation of correlated sets of PDFs at different perturbative orders [103].

The nuisance parameter representation of  $\chi^2$  in Eq. 18 is derived assuming symmetric experimental errors, however, the published systematic uncertainties are often asymmetric. HERAFitter provides the possibility to use asymmetric systematic uncertainties. The implementation relies on the assumption that asymmetric uncertainties can be described by a parabolic function. The nuisance parameter in Eq. 18 is modified as follows

$$\gamma_i^i \to \omega_i^i b_i + \gamma_i^i,$$
 (19)

where the coefficients  $\omega_i^i$ ,  $\gamma_i^i$  are defined from the maximum and minimum shifts of the cross sections due to a variation of the systematic uncertainty  $j, S_{ij}^{\pm}$ ,

$$\omega_{j}^{i} = \frac{1}{2} \left( S_{ij}^{+} + S_{ij}^{-} \right), \qquad \gamma_{j}^{i} = \frac{1}{2} \left( S_{ij}^{+} - S_{ij}^{-} \right).$$
 (20)

The results of a OCD fit depend not only on the input data but also on the input parameters used in the theoretical calculations. Nowadays, PDF groups address the impact of the choices of theoretical parameters by providing alternative PDFs with different choices of the mass of the charm quarks, m<sub>c</sub>, mass of the bottom quarks,  $m_b$ , and the value of  $\alpha_{\rm s}(m_Z)$ . Other important aspects are the choice of the functional form for the PDFs at the starting scale and the value of the starting scale itself. HERAFitter provides the possibility of different user choices of all these inputs.

### 709 5.5 Bayesian Reweighting Techniques

As an alternative to performing a full QCD fit, HERAFitter 711 allows the user to assess the impact of including new data in an existing fit using the Bayesian Reweighting technique. The method provides a fast estimate of the impact of new data on PDFs. Bayesian Reweighting was first proposed for PDF sets delivered in the form of MC replicas by [99] and More recently, a method to perform Bayesian Reweighting studies starting from PDF fits for which uncertainties are provided in the eigenvector representation has been also developed [101]. The latter is based on generating replica sets by introducing Gaussian fluctuations on the central PDF set Since the MC method requires large number of replicas, 722 with a variance determined by the PDF uncertainty given the eigenvector representation is a more convenient way 723 by the eigenvectors. Both reweighting methods are imple-

> The Bayesian Reweighting technique relies on the fact that MC replicas of a PDF set give a representation of the probability distribution in the space of PDFs. In particular,

the PDFs are represented as ensembles of  $N_{\text{rep}}$  equiprobable 737 **6 Alternatives to DGLAP Formalism** (i.e. having weights equal to unity) replicas,  $\{f\}$ . The central value for a given observable,  $\mathcal{O}(\{f\})$ , is computed as the 738 QCD calculations based on the DGLAP [11-15] evolution average of the predictions obtained from the ensemble as

$$\langle \mathcal{O}(\{f\}) \rangle = \frac{1}{N_{\text{rep}}} \sum_{k=1}^{N_{\text{rep}}} \mathcal{O}(f^k),$$
 (21)

and the uncertainty as the standard deviation of the sample. 745

Upon inclusion of new data the prior probability distribution, given by theoriginal PDF set, is modified according to Bayes Theorem such that the weight of each replica,  $w_k$ , is updated according to

$$w_k = \frac{(\chi_k^2)^{\frac{1}{2}(N_{\text{data}} - 1)} e^{-\frac{1}{2}\chi_k^2}}{\frac{1}{N_{\text{rep}}} \sum_{k=1}^{N_{\text{rep}}} (\chi_k^2)^{\frac{1}{2}(N_{\text{data}} - 1)} e^{-\frac{1}{2}\chi_k^2}},$$
(22)

where  $N_{\rm data}$  is the number of new data points, k denotes the specific replica for which the weight is calculated and  $\chi_k^2$  is the  $\chi^2$  of the new data obtained using the k-th PDF replica. Given a PDF set and a corresponding set of weights, which describes the impact of the inclusion of new data, the prediction for a given observable after inclusion of the new data can be computed as the weighted average.

$$\langle \mathscr{O}(\{f\}) \rangle = \frac{1}{N_{\text{rep}}} \sum_{k=1}^{N_{\text{rep}}} w_k \mathscr{O}(f^k).$$
 (23)

To simplify the use of a reweighted set, an unweighted set (i.e. a set of equiprobable replicas which incorporates the information contained in the weights) is generated according to the unweighting procedure described in [104]. The number of effective replicas of a reweighted set is measured by its Shannon Entropy [105]

$$N_{\text{eff}} \equiv \exp\left\{\frac{1}{N_{\text{rep}}} \sum_{k=1}^{N_{\text{rep}}} w_k \ln(N_{\text{rep}}/w_k)\right\},\,$$
(24)

set containing the same amount of information. This num-  $\tau \tau 0$  tion  $\sigma_0$ ,  $\tau 0$ , and  $\tau 0$  are parameters of the model fitted to the ber of effective replicas,  $N_{\rm eff}$ , gives an indicative measure of 771 DIS data. This model gives exact Bjorken scaling when the the optimal size of an unweighted replica set produced with 772 dipole size r is small. the reweighting/unweighting procedure. No extra information is gained by producing a final unweighted set that has a 773 BGK model: The BGK model is a modification of the GBW number of replicas (significantly) larger than  $N_{\text{eff}}$ . If  $N_{\text{eff}}$  is 774 model assuming that the spacing  $R_0$  is inverse to the gluon much smaller than the original number of replicas the new 775 distribution and taking into account the DGLAP evolution data have great impact, however, it is unreliable to use the 776 of the latter. The gluon distribution, parametrised at some new reweighted set. In this case, instead, a full refit should 777 starting scale by Eq. 12, is evolved to larger scales using be performed.

939 equations are very successful in describing all relevant hard scattering data in the perturbative region  $Q^2 \gtrsim$  few GeV<sup>2</sup>. At small-x and small- $Q^2$  DGLAP dynamics may be modi-(21) 742 fied by saturation and other (non-perturbative) higher-twist effects. Different approaches alternative to the DGLAP formalism can be used to analyse DIS data in HERAFitter. These include several dipole models and the use of transverse momentum dependent, or unintegrated PDFs (uPDFs).

### 747 6.1 Dipole Models

The dipole picture provides an alternative approach to proton-(22) virtual photon scattering at low x which can be applied to 750 both inclusive and diffractive processes. In this approach, the virtual photon fluctuates into a  $q\bar{q}$  (or  $q\bar{q}g$ ) dipole which interacts with the proton [106, 107]. The dipoles can be considered as quasi-stable quantum mechanical states, which have very long life time  $\propto 1/m_p x$  and a size which is not 755 changed by scattering with the proton. The dynamics of the interaction are embedded in a dipole scattering amplitude.

Several dipole models, which assume different behaviours of the dipole-proton cross section, are implemented in HERA-759 Fitter: the Golec-Biernat-Wüsthoff (GBW) dipole satura-760 tion model [28], a modified GBW model which takes into account the effects of DGLAP evolution, termed the Bartels-762 Golec-Kowalski (BGK) dipole model [30] and the colour glass condensate approach to the high parton density regime, named the Iancu-Itakura-Munier (IIM) dipole model [29].

GBW model: In the GBW model the dipole-proton cross section  $\sigma_{dip}$  is given by

$$\sigma_{\text{dip}}(x, r^2) = \sigma_0 \left( 1 - \exp\left[ -\frac{r^2}{4R_0^2(x)} \right] \right), \tag{25}$$

r where r corresponds to the transverse separation between (24) 766 the quark and the antiquark, and  $R_0^2$  is an x-dependent scale 767 parameter which represents the spacing of the gluons in the proton.  $R_0^2$  takes the form,  $R_0^2(x) = (x/x_0)^{\lambda} 1/\text{GeV}^2$ , and is which corresponds to the size of a refitted equiprobable replica69 called the saturation radius. The cross-section normalisa-

778 DGLAP evolution.

BGK model with valence quarks: The dipole models are 819 The masses of the quarks are explicitly included as paramvalid in the low-x region only, where the valence quark con- 820 eters of the model. In addition to  $\gamma^*g^* \to q\bar{q}$ , the contributribution to the total proton momentum is 5% to 15% for x 821 tion from valence quarks is included via  $\gamma^* q \to q$  by using a from 0.0001 to 0.01 [108]. The inclusive HERA measure- 822 CCFM evolution of valence quarks [129–131]. ments have a precision which is better than 2%. Therefore, HERAFitter provides the option of taking into account the 823 CCFM Grid Techniques: The CCFM evolution cannot be contribution of the valence quarks

IIM model: The IIM model assumes an expression for the dipole cross section which is based on the Balitsky-Kovchegov equation [109]. The explicit formula for  $\sigma_{dip}$  can be found in [29]. The alternative scale parameter  $\tilde{R}$ ,  $x_0$  and  $\lambda$  are fitted parameters of the model.

### 6.2 Transverse Momentum Dependent PDFs

QCD calculations of multiple-scale processes and complex final-states can necessitate the use of transverse-momentum dependent (TMD) [8], or unintegrated parton distribution and parton decay functions [110-118]. TMD factorisation has been proven recently [8] for inclusive DIS. TMD factorisation has also been proven in the high-energy (small-x) limit [119–121] for particular hadron-hadron scattering processes, like heavy flavour, vector boson and Higgs production.

In the framework of high-energy factorisation [119, 122, 123] the DIS cross section can be written as a convolution in both longitudinal and transverse momenta of the TMD parton distribution function  $\mathcal{A}(x, k_t, \mu_F^2)$  with the off-shell parton scattering matrix elements as follows

$$\sigma_j(x,Q^2) = \int_x^1 dz \int d^2k_t \ \hat{\sigma}_j(x,Q^2,z,k_t) \ \mathscr{A}\left(z,k_t,\mu_F^2\right),$$
 (26)

where the DIS cross sections  $\sigma_i(j=2,L)$  are related to the structure functions  $F_2$  and  $F_L$  by  $\sigma_i = 4\pi^2 F_i/Q^2$ , and the hard-scattering kernels  $\hat{\sigma}_i$  of Eq. 26 are  $k_t$ -dependent.

The factorisation formula in Eq. 26 allows resummation of logarithmically enhanced small-x contributions to all orders in perturbation theory, both in the hard scattering coef- 849 Functional Forms for TMD parametrisation: For the startficients and in the parton evolution, fully taking into account  $_{850}$  ing distribution  $\mathcal{A}_0$ , at the starting scale  $Q_0^2$ , the following the dependence on the factorisation scale  $\mu_F$  and on the fac- 851 form is used: torisation scheme [124, 125].

Phenomenological applications of this approach require matching of small-x contributions with finite-x contributions. To this end, the evolution of the transverse momentum de- where  $\sigma^2 = Q_0^2/2$  and N, B, C, D, E are free parameters. Vapendent gluon density A is obtained by combining the re- 853 lence quarks are treated using the method of Ref. [129] as summation of small-x logarithmic corrections [126–128] with a starting distribution taken medium-x and large-x contributions to parton splitting [11, 855 from any collinear PDF and imposition of the flavour sum 14, 15] according to the CCFM evolution equation [23–26]. 856 rule at every scale p.

scheme, using the boson-gluon fusion process  $(\gamma^*g^* \to q\bar{q})$ . SSS Fitter tools or with TMDplotter [35].

written easily in an analytic closed form. For this reason, a MC method is employed, which is, however, time-consuming and thus cannot be used directly in a fit program.

Following the convolution method introduced in [131, 132], the kernel  $\tilde{\mathscr{A}}(x'', k_t, p)$  is determined from the MC solution of the CCFM evolution equation, and then folded with a non-perturbative starting distribution  $\mathcal{A}_0(x)$ 

$$x\mathscr{A}(x,k_t,p) = x \int dx' \int dx'' \mathscr{A}_0(x') \widetilde{\mathscr{A}}(x'',k_t,p) \,\delta(x'x''-x)$$
$$= \int dx' \mathscr{A}_0(x') \frac{x}{x'} \,\widetilde{\mathscr{A}}\left(\frac{x}{x'},k_t,p\right), \tag{27}$$

where  $k_t$  denotes the transverse momentum of the propagator gluon and p is the evolution variable.

The kernel  $\tilde{\mathscr{A}}$  incorporates all of the dynamics of the evolution. It is defined on a grid of  $50 \otimes 50 \otimes 50$  bins in 835  $x, k_t, p$ . The binning in the grid is logarithmic, except for the longitudinal variable x for which 40 bins in logarithmic spacing below 0.1, and 10 bins in linear spacing above 0.1

Calculation of the cross section according to Eq. 26 involves a time-consuming multidimensional MC integration, which suffers from numerical fluctuations. This cannot be 842 employed directly in a fit procedure. Instead the following 843 equation is applied:

$$\sigma(x,Q^2) = \int_x^1 dx_g \mathscr{A}(x_g, k_t, p) \hat{\sigma}(x, x_g, Q^2)$$
$$= \int_x^1 dx' \mathscr{A}_0(x') \tilde{\sigma}(x/x', Q^2), \tag{28}$$

where first  $\tilde{\sigma}(x',Q^2)$  is calculated numerically with a MC integration on a grid in x for the values of  $Q^2$  used in the 846 fit. Then the last step in Eq. 28 is performed with a fast numerical Gauss integration, which can be used directly in the

$$x\mathcal{A}_0(x,k_t) = Nx^{-B}(1-x)^C \left(1 - Dx + E\sqrt{x}\right)$$
$$\times \exp[-k_t^2/\sigma^2], \tag{29}$$

The cross section  $\sigma_j$ , (j=2,L) is calculated in a FFN 857 The TMD parton densities can be plotted either with HERA-

The consistency of the 911 144] and at the LHC [145], using measurements from ATmeasurements and the theory can be expressed by pulls, de- 912 LAS [94, 136]. These PDFs can be used to study predictions the uncorrelated error of the data. In each kinematic bin of 914 provides the possibility to perform various benchmarking 916 liders as demonstrated by QCD studies at the LHeC [147].

# 917 9 Summary

918 HERAFitter is the first open-source platform designed for 919 studies of the structure of the proton. It provides a unique and flexible framework with a wide variety of QCD tools to facilitate analyses of the experimental data and theoretical calculations.

The HERAFitter code, in version 1.1.0, has sufficient options to reproduce the different theoretical choices made in MSTW, CTEO and ABM fits. This will potentially make it a valuable tool for benchmarking and understanding differences between PDF fits. Such a study would however 928 need to consider a range of further questions, such as the 929 choices of data sets, treatments of uncertainties, input pa- $_{930}$  rameter values,  $\chi^2$  definitions, etc.

The further progress of HERAFitter is driven by the latest 932 QCD advances in theoretical calculations and in the preci-933 sion of experimental data.

934 Acknowledgements HERAFitter developers team acknowledges the kind hospitality of DESY and funding by the Helmholtz Alliance "Physics at the Terascale" of the Helmholtz Association.
